Dr. Vernon P. Thompson, Los Angeles: The supracondylar or transcondylar fracture is above the elbow joint. If the surgeon does not manhandle the elbow joint with repeated forcible manipulations, or insult it by open surgery, there will be useful elbow motion. There may be deformity; there may be limitation, but there will be useful elbow-joint motion. The other fractures of the elbow, which are internal derangements, require as near anatomic reposition as possible, with maintenance by whatever means necessary, and useful elbow-joint function will be gained. The factors of growth that Dr. Blount has stressed for many years in treatment of children's fractures are especially helpful with the rather uniform lack of anatomic replacement of the supracondylar fracture. Cubitus varus and rotational disalignment occur frequently. Reduction and maintenance still need to be improved. In the closed management of the supracondylar fracture, the surgeon must choose either manipulative reduction or traction. If he chooses closed reduction, it should be successful with gentleness and without repetition; he must secure not only alignment but also bony apposition and sufficient flexion to maintain fixation. If the fracture is sufficiently high, so that one has two prongs, one usually longer than the other, one of which slips in front or in back, it causes rotational disalignment, with loss of carrying angle; then he must take his hat off to Dr. John Dunlop, who has shown us for many years in Los Angeles how useful traction is. With traction the surgeon need not insult the joint; he needs only to obtain alignment. He does not have to secure firm bony apposition. But secure maintenance by callus requires at least two and often three weeks. I am happy to have read Dr. Blount's appreciation of the value of this means of reduction. There is a poor cosmetic effect in loss of carrying angle and the limitation of extension. I have seen few of these elbows that have hyperextension. Forcible attempts to correct the deformity may disturb the alignment, resulting in a worse deformity through interference with growth. After healing and return of motion, corrective osteotomy may be performed if the deformity warrants it.

---

Dr. Lewis M. Overton, Albuquerque, N. M.: I should like to congratulate Dr. Blount and his co-authors on a timely and pertinent discussion of an important subject. I heartily agree with their conservative approach to the problem; however, there are some difficulties that arise in the management of these injuries in which my experience has been somewhat different from theirs. Oblique supracondylar fractures, which are not infrequent in children, often present definite problems. The obliquity is usually downward and lateral. This produces a tendency for the lower fragments to displace medially, as well as posteriorly. In most instances the fractured surfaces are rough and somewhat splintered. This will allow some locking of these fragments when the elbow is manipulated, but, if any rotation occurs, the locking is not sufficient to prevent a loss of position. The only way in which one can be sure of preventing the loss of position in these fractures is by immobilizing the elbow in a plaster cast and anchoring it to the body with a shoulder spica cast, which has been described by Conwell and Key. It is interesting to note that the displaced radial head, which is free in the joint when completely reduced or satisfactorily reduced, will give an excellent result in children. Fractures of the upper third of the ulna, with dislocation of the head of the radius, or so-called Monteggia's fracture, are not common in children but, when present, will result in considerable disability, if treatment is not adequate. I cannot agree with the authors that this injury is not disabling. It is necessary to secure a stable radial head, if a satisfactory function is to be obtained. Failure to do so will result in a valgus deformity of the elbow, radial deviation of the hand, and an unstable elbow joint. This is particularly true in young children. Late open reduction and reconstruction of the annular ligament are not entirely satisfactory. For this reason, one must stress the early reduction and repair of the ligament, if the radial head remains unstable after closed reduction.

Dr. Walter P. Blount, Milwaukee: The difficult supracondylar fracture, and particularly the oblique fracture, can be well treated by traction, as both discussants have pointed out. I am grateful to Dr. Thompson for emphasizing this point. Dr. Overton gets very good results with plaster fixation. In my experience, if the child is let out of the hospital, he will wiggle in the plaster and lose the position of an oblique fracture. I treat these difficult fractures with traction somewhat according to Dunlop's method rather than with plaster. But use whichever method is best in your hands and conservative measures when possible. A Monteggia fracture in children is interesting. I agree with Dr. Overton that the necessary point is to get the radial head back into position. The incision of Boyd is ideal for this purpose. One cannot keep the radial head away from the capitellum once the orbicular ligament is cut out of the way. Then the radius splints the ulna, and internal fixation is almost never necessary in children. Like Dr. Overton I would warn you not to do a late reduction of the dislocation. After three months, let the displaced radial head alone, whatever the cause, because function remains excellent in spite of the appearance. After this length of time, an open reduction of the radial head in a child leads to limitation of motion and permanent disability. The radial head may be removed when the child is full grown. Pain after reduction of a fracture in a child should be controlled by aspirin; opiates should not be necessary. If opiates are required, it usually means that there is something wrong with the reduction or the fixation.

CLINICAL IMPLICATIONS OF MARFAN'S SYNDROME

Arthur Alan Fischl, M.D.

and

Jack Ruthberg, M.D., New York

The syndrome was first reported in the literature by A. B. Marfan[1] in 1896 as *pieds d'aragne* (spider feet). Méry and Babonneix[2] suggested the name hyperchondroplasia. C. Achard[3] in 1902 because of the spider-like appearance of the extended fingers called it arachnodactyly. Since that time there have been over 200 cases reported in the literature, particularly the French and German. It was not until 1926 that Piper and Irvine-Jones,[4] who associated the syndrome with congenital heart disease, published the first paper to appear in American journals. A few more cases have been added since.[5] We feel, however, that the condition is much commoner than is indicated. Very few autopsies have been reported, only about 13 in over 200 clinical reports. Reports on examinations of the eye are rare.

REPORT OF CASES

Case 1.—A 24 year old white woman was seen, complaining of severe chest pains and "palpitations." These had been present for two years and had occurred with increasing frequency in the six months prior to the time we saw her. They were aggravated by excitement and often appeared nocturnally. During these attacks, she became weak and dizzy and perspired freely.

Physical examination revealed a slender girl with long arms and legs, the hands reaching almost to the knees. The wrists were long and flat, the face was narrow, long and thin. Pupillary reactions were present but sluggish. There was a definite tremulous motion of the irises on movement of the eyeballs. The fundi were visualized with difficulty, and the lenses seemed subluxated. The general facial expression was melancholic.

A moderate muscle weakness of the face and shoulder girdle was present. The hard palate was high and arched. The ears were long and pointed. The chest was long, narrow and funnel shaped. The left border of the heart extended 18 cm. from the midsternal line, with the apex palpable in the left eighth interspace, with a regular sinus rhythm. The apex impulse was heaving, with a precordial bulge. A systolic blow was present at the apex, and, in addition, aortic systolic and aortic diastolic murmurs were heard. The blood pressure was 145/20. The lower extremities presented the same picture as the upper. The legs were long and thin, the patellas being elevated, with long and tapered toes. Slight webbing of the toes and fingers existed.

Assistant Clinical Professor of Medicine, New York Medical College (Dr. Fischl), and Assistant Visiting Physician, Queens General Hospital (Dr. Ruthberg).

From the Department of Medicine, Queens General Hospital, James R. Reuling, M.D., Director.

J.: Muscular and Skeletal Changes in Arachnodactyly, Arch. Surg. **39**: 741 (Nov.) 1939. (*e*) Green, H., and Emerson, P. W.: Arachnodactylia: Clinical Report of 6 Cases, Arch. Pediat. **60**: 299 (June) 1943.

Roentgenograms of the chest revealed an enlarged left ventricle and auricle, with fulness of the middle third, suggestive of a double valve lesion. An esophagram confirmed the enlarged left auricle. Roentgenograms revealed notching of the ribs as seen in coarctation of the aorta (fig. 1).

Repeated electrocardiograms showed a progressive increase in tachycardia from 110 to 130. The ST segments showed a progressive depression with gradual inversion of the T waves in the standard limb leads. The P wave was large and broad. A progressive right axis shift was noted over four months. The patient had attacks of paroxysmal tachycardia which failed to respond to quinidine. These, however, would sometimes break spontaneously. The patient improved after three weeks of bed rest.

She was readmitted six months later in poor condition. The palpitations and precordial pain had become more frequent and severe. Blood pressure in the arm was 140/70 and in the leg 120/70. A loud to-and-fro murmur was heard over the entire precordium. The patient had a high fever, with the electrocardiogram showing an active carditis with pericarditis. Therapy with salicylates, digitalis and penicillin was of no avail. The patient became mentally confused and disoriented, left the hospital and expired at home.

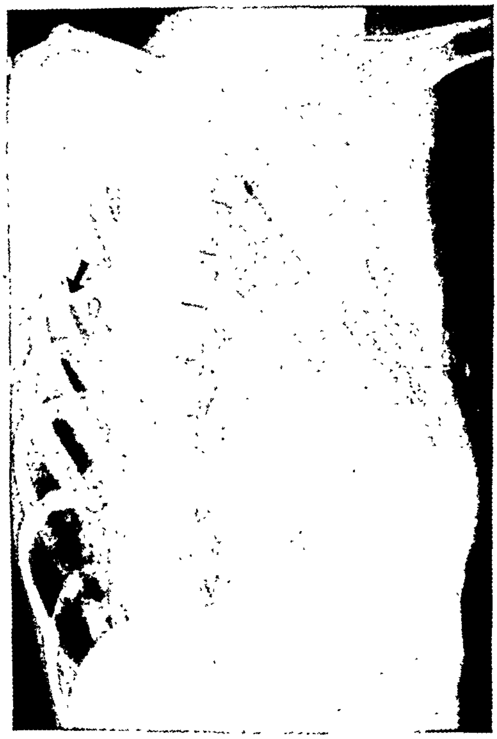

Fig. 1.—Right oblique view (with barium) showing enlarged auricles and notching of ribs.

At autopsy[6] it was observed that there were several petechiae and a left conjunctival hemorrhage The palate was high and arched. The ears were long and pointed. The limbs were long and slender with increased webbing between the fingers and toes. The pericardium was dilated to accommodate a decidedly enlarged heart. The right pleural cavity contained about a liter of clear yellow fluid; the left was obliterated by adhesions. The weights of various organs were heart 750 Gm.; right lung 680 Gm.; left lung 600 Gm.; liver 1,950 Gm.; spleen 175 Gm.; right kidney 160 Gm.; left kidney 160 Gm.

Both lenses of the eyes were small and appeared loosely attached (fig. 2). The ciliary body was narrow. The retina was attached. The optic nerve head suggested a mild atrophy extending to the lamina cribrosa. The ora serrata showed atrophic changes (fig. 2). Microscopic examination of the eye showed round cell infiltration in the region of the optic head, with a suggestion of atrophy of the nerve. The choroid showed round cell infiltration and irregularity of pigment dispersion. The retina showed no pigment migration and the layers were intact, with apparent diminution of ganglion cells. The pars plana showed pigment in its depths. The ciliary body was atrophic with hyalinization of the ciliary processes. The iris showed evidence of loss of furrows and irregular pigmention in one epithelial layer. The filtration angle was normal.

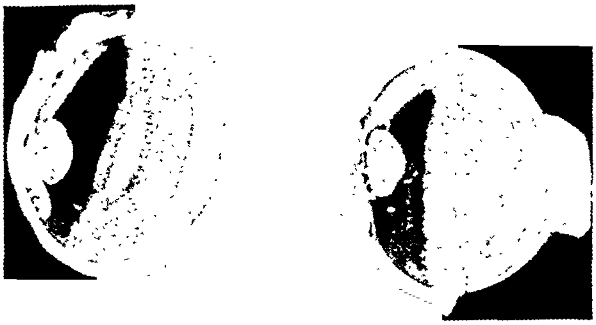

Fig. 2.—Cut section of eyes. Note the small spherical lens.

The thyroid gland was normal. The lungs were congested and wet at the bases, with a deep red, firm area at the base of the left lower lobe. In the artery to the left lower lobe an antemortem thrombus was found. The heart was enormously dilated and also hypertrophied. The valves were insufficient because of pronounced dilatation of the valve rings. The myocardium was soft and flabby. The pulmonic cusps were separated, and the pulmonary conus was widened. The aorta showed a large saccular aneurysm beginning at the base of the aorta and involving the ascending aorta (fig. 3). Just beyond the left subclavian artery was a coarctation of the aorta. The ductus arteriosus was a fibrous cord at this point. Microscopic examination of the heart and aorta showed a moderate fatty degeneration of the myocardium with a moderate diffuse fibrosis. The aorta at the coarctation site showed a definite disorganization of the elastica, particularly at the inner aspect of the aorta. There was a diffuse fibrosis and hyalinosis in this area. A fine fibrillar elastic layer occupied the region of the intima and subintima. The elastic tissue was not well formed or stained throughout the media. The aneurysm itself showed a dense collagenous zone in the adventitia. Foci of necrosis and degeneration were noted throughout the media. The elastic coat was incomplete and disorganized. Some cystic areas were noted in the media with mucinous-like contents (fig. 4). The adventitia coat was dense and hyalinized. No inflammatory lesions were observed.

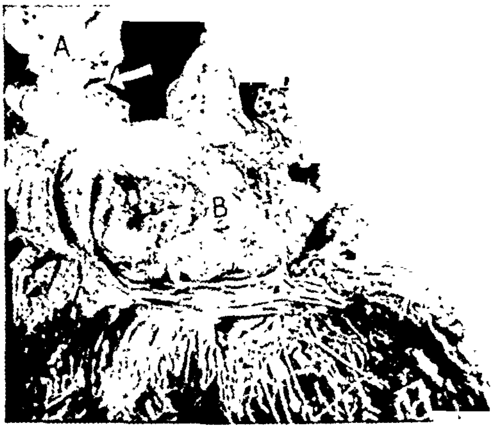

Fig. 3.—Heart and aorta. *A*, the aortic coarctation site; the ductus arteriosus was a fibrous cord at this point (arrow). *B*, the saccular aneurysm of the ascending aorta. Note the dilatation of the aortic valve ring.

---

[6] The autopsy in case 1 was performed by Drs. J. Ruthberg, A. Angrist and L. Burson.

The liver, spleen and kidneys showed a chronic passive congestion. One ovary was enlarged and, on section, showed a soft mass containing some hair. A chronic salpingitis was present. Microscopic examination showed chronic passive congestion of the liver, kidneys and spleen, with a dermoid cyst of the ovary and chronic salpingitis.

The final postmortem diagnosis was coarctation of the aorta; sacculated aneurysm of the base of aorta; myocardial hypertrophy and dilatation; chronic passive congestion of liver, spleen, kidneys and lungs; arachnodactyly (Marfan's syndrome); microlentis with subluxation; dermoid ovarian cyst; chronic salpingitis and antemortem embolus to the left lung.

Case 2.—A 32 year old Negress was first seen in June, with a history of vaginal discharge, chills and fever of three months' duration. A temperature of 101 F. was found, with a tender mass in the right adnexa. A cystic ovary with a chronic salpingitis was observed. The patient was readmitted several times with cough, hemoptysis and night sweats. A retrograde urogram showed an ectopic left kidney with hydronephrosis. Blood pressure was 105/68. The face was elongated, with long pointed ears. The pupils reacted to light and accommodation. A tremulous motion of the iris was noted (iridodonesis). The lens was deep and subluxated, creating a deep anterior chamber. The extremities were noteworthy in that the arms and legs were extremely long, with the fingers reaching to the knees. A pronounced webbing was present between the fingers. Both patellas were abnormally high, being about 3 cm. above the normal position. The feet were long in proportion. A roentgenogram of the chest revealed congenital abnormalities of the ribs. The left border of the heart was straightened, and a cervical rib was present. The sacrum showed spina bifida occulta. The electrocardiogram was normal. The patient was treated with sulfadiazine and responded readily. The clinical impression was Marfan's syndrome, pyelonephritis, congenital deformity of the kidneys and probable heart disease (congenital).

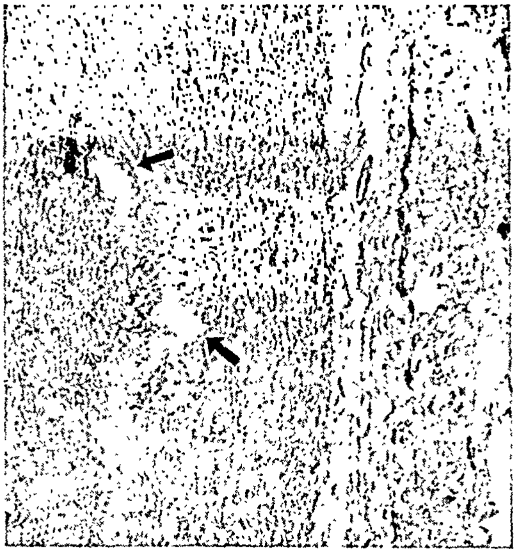

Fig. 4.—Cystic areas of degeneration in the aorta. These cysts are filled with mucoid material.

Case 3.—A 21 year old white man was seen April 11, 1946, complaining of chills and fever and diarrhea. Several days earlier he had had a tooth extracted, followed by edema of the face. Physical examination revealed a temperature of 103 F., pulse 80, respirations 22, with blood pressure normal. A purulent nasal discharge was present. A high palate was noted. The pupils were small with a pronounced myopia. The face was long with pointed ears. A funnel chest was present. The heart showed a regular rhythm, with the aortic second sound greater than the pulmonic second sound. No murmurs were heard. There was an absent lumbar curve. The extremities were exceedingly long with distinct webbing of the fingers. The joints were hyperflexible. The fingers reached almost to the knees. The patellas were higher than usual. Spinal tap showed 42 cells. A roentgenogram showed a pansinusitis, high patellas and abnormally long metacarpals and phalanges. White blood cells numbered 14,700, with 82 per cent polymorphonuclear cells. The patient was treated with sulfadiazine and improved.

COMMENT

In a review of this syndrome, our best knowledge comes from a study of autopsy material. Only a few autopsies have been done in the 200 or so cases reported. In 1914 Börger [7] found a patent foramen ovale and a two lobed right lung. Salle [8] reported a 6 week old male with an enlarged heart due to patent foramen ovale. Piper and Irvine-Jones [4] reported a 21 month old female who had a systolic thrill and a presystolic and systolic basal murmur. At postmortem examination, they found an interauricular septal defect with failure of division of the lobes of the lungs. Olcott's [9] case showed fenestrations of the mitral valve and a small frontal lobe of the brain. Futcher and Southworth [5c] reviewed three autopsies done in 1938. Pneumonia was the common factor in death. Baer, Taussig and Oppenheimer [10] in 1943 described two cases with aneurysmal dilatation of the ascending aorta proximal to the aortic arch, one of which had a dissecting aneurysm. Necropsy showed cystic areas in the media with rupture of the aorta. Etter and Glover [11] reported a massive hemopericardium and a dissecting aneurysm of the ascending aorta with rupture into the pericardial sac. Green and Emerson [5c] reported one lobe in the left lung and a small right middle lobe.

Rambar and Denenholz [12] had a patient who revealed an absence of dilator pupillae muscles, accounting for their inability to dilate with atropine. These eye observations may indicate that the aberration of development occurred during the sixth month of fetal life. There are numerous theories: a "constitutional aberration of anlage" [13] in Marfan's syndrome; that the condition has a neurological basis allied to syringomyelia; [14] some hereditary factor with a selective dystrophy of mesodermal tissues.[15] Rambar and Denenholz also felt that there was a defective anlage with a failure of development, and they cite the absence of dilator pupillae. Schilling [16] emphasized the hormonal disturbance, particularly hyperfunction of the eosinophilic cells of the pituitary. This factor was discredited by Young,[17] who felt that the onset of Marfan's syndrome was in utero and that, therefore, the endo-

17. Young, M. L.: Arachnodactyly, Arch. Dis. Childhood **4**: 190 (Aug.) 1929.

crines could not affect the fetus because of compensation by the mother. The theory of a congenital muscular dystrophy was also discredited by Young, since he reported normal muscular electrical response in Marfan's syndrome. The muscular disturbance in arachnodactyly is not progressive muscular atrophy. Piper and Irvine-Jones felt that there was a pathological defect in the germ plasma. The hereditary factor is mentioned by almost all writers.[18] Rados [19] collected 204 cases from the literature, 28.9 per cent of which showed a hereditary background and 18.8 per cent a questionable tendency.

The symptoms and signs presented by these patients are best described by the systems involved. The bony structures are considerably involved, the fingers and toes being long and tapering. The metacarpals and metatarsals are involved the most. There is a decided reduction of subcutaneous fat, giving the effect of malnutrition. These patients are usually "double jointed" due to relaxation of the ligaments. The ears are, as a rule, extremely prominent with pointed tips. The palate is high and arched. Kyphosis and scoliosis with sternal deformities are often present. Webbing of the fingers is common. The facial appearance is peculiar. A long drooping jaw, eyeglasses, thin face and long ears give the patient a mournful expression. The tendency to poor development of the secondary sexual characteristics has been noted. The basal metabolic rate may be decreased. Pneumonia is frequent as a cause of death, probably due to the chest and spine deformities plus the incidence of anomalies of the lungs. Mental retardation is rare. The eye findings are of significance and are important in the diagnosis. They are deeply set and myopic. About half the cases have a bilateral dislocation or subluxation of the lens. The pupils are in midconstriction, dilate poorly with atropine, and there is an associated iridodonesis. Greater stress should be placed on the high incidence of congenital heart disease. Abnormalities of the heart and lungs are present in about 50 per cent of the cases. Systolic murmurs are common (about 65 per cent). Interauricular septal defects are not unusual. They were described in three of eight autopsies. Congenital aneurysm of the aorta with subsequent rupture is common, and coarctation of the aorta, as shown in our case, is found in increasing instances. This should be borne in mind, for such lesions are often silent until later in life.

SUMMARY

Three cases of Marfan's syndrome are presented, one with an autopsy. A review of the literature is presented, with stress on the high incidence of cardiac malformation.

SECOND ATTACKS OF POLIOMYELITIS

REPORT OF A CASE WITH AUTOPSY FINDINGS

Archibald L. Hoyne, M.D., Chicago
and
Irving Lipton, M.D., Van Nuys, Calif.

Second attacks of poliomyelitis have been reported infrequently. In 1948, Fox and his associates [1] reviewed the literature, noted 21 second attacks of poliomyelitis, and added one. Fifteen other cases were listed as doubtful. Besides those series, seven reliable and two probable second attacks have been recorded. Bridges and others [2] reported four second attacks and two questionable ones. Alves and Pugh,[3] Wyllie,[4] and Ashley,[5] have each reported one case. Thus, to date there have been 29 second attacks of poliomyelitis and 17 doubtful second attacks cited in the literature. Careful analysis of the reported second attacks reveals that in only one instance previously regarded as authentic did the second attack terminate fatally. In no case have autopsy findings been reported. Furthermore, in the fatal case cited by Fischer and Stillerman [6] it is questionable whether the patient ever had the disease previously. In that instance the supposed first attack was nonparalytic, and examination of the spinal fluid showed only two cells.

Here we wish to present a case in which the second attack terminated fatally and a complete pathological examination was performed.

REPORT OF CASE

E. T., a white woman aged 31, was admitted to Municipal Contagious Disease Hospital on Aug. 21, 1949, with a diagnosis of bulbar poliomyelitis. The past history revealed the usual childhood diseases, routine immunizations, and a tonsillectomy and adenoidectomy. At the age of 26 she was hospitalized in Pittsburgh, where the diagnosis was poliomyelitis, with paralysis of the left leg. On that occasion the patient "was told by her physician that her spinal fluid showed the typical findings of poliomyelitis." Following her recovery, she had residuals of marked weakness and moderate atrophy of the left leg. She eventually regained her general health but walked with a limp.

Former Medical Superintendent (Dr. Hoyne), and former Assistant Medical Superintendent (Dr. Lipton), Municipal Contagious Disease Hospital, Chicago Health Department.

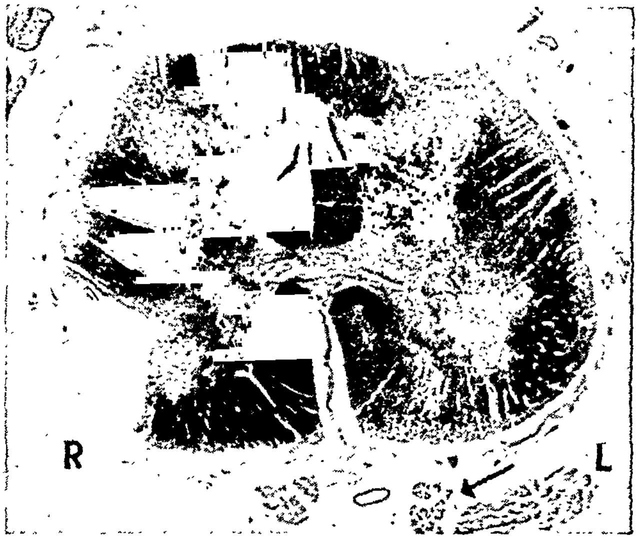
5. Ashley, G.: Poliomyelitis: Second Attack; Report of Case, J. Kansas M. Soc. **48**: 406, 1947.

6. Fischer, A. E., and Stillerman, M.: Does Attack of Acute Anterior Poliomyelitis Confer Adequate Immunity? Report of 4 Second Attacks in New York City in 1935, J. A. M. A. **110**: 569 (Feb. 19) 1938.

Two days previous to the present admission, the patient developed a low-grade fever and severe frontal headaches. These symptoms persisted, and 24 hr. after the onset she experienced difficulty in swallowing and noticed that her voice sounded different. On the morning of hospitalization she had complained of weakness in the neck and back.

Physical Examination.—On admission, physical examination revealed a well-developed and well-nourished 31-year-old woman with slurred, nasal speech. Temperature was 98.6 F., pulse 104 a minute, and respirations 24 a minute. She was rational and well-oriented. Examination of the eyes, ears, and nose was noncontributory. Nuchal rigidity was absent, but the patient exhibited moderate head drop. There was no evidence of facial paralysis. The tongue was coated and deviated slightly to the right on protrusion. The tonsils had been enucleated, and there was a moderate amount of mucus filling the oropharynx. Heart and lungs were clear on percussion and auscultation. Abdominal examination disclosed no abnormalities. The upper extremities were normal in all respects. Although the lower extremities were of equal length, there was moderate atrophy of the left thigh and slight atrophy of the left leg as a result of the first attack of poliomyelitis. The left lower extremity also showed marked weakness in comparison with the right. Deep reflexes were equal and active, with the exception of the left patellar and ankle jerk, which were absent. The abdominal reflexes were active on the right side but absent on the left. Both the Kernig and Babinski signs were negative.



Photomicrograph of section of spinal cord at level of the first and second lumbar segments. Arrow points to anterior root which shows complete demyelinization of the nerve fibers on the site of the old lesion (left). In the anterior horns proper, no differences were seen between the left and right sides. This is because of the recent changes characterized by extreme destruction of the motor nerve cells and the presence of numerous inflammatory cells.

Laboratory Data.—Admission nose and throat cultures were negative for both diphtheria and hemolytic streptococci. The urine was acid with a specific gravity of 1.015. Urine showed 2 plus albumin, no sugar, and no blood. Microscopic examination revealed many pus cells but no casts. Unfortunately, the report of the white blood count was lost, but the differential count disclosed 68% polymorphonuclear cells and 32% lymphocytes. The cerebrospinal fluid was released under slightly increased pressure and appeared clear. The cell count was 140 per cubic millimeter. A smear showed many white blood cells, 90% of which were polymorphonuclear cells and 10% lymphocytes. There were no organisms. The Pandy test was 4 plus. Chlorides were 728 mg. per 100 cc., sugar was 74 mg. per 100 cc., and the total protein was 72 mg. per 100 cc. The spinal fluid culture was negative.

Treatment was entirely symptomatic. The foot of the bed was raised, and suction was used as necessary. Continuous intravenous fluids were started. On the second hospital day the temperature gradually rose to 102.4 F., pulse to 130 a minute, and respirations to 38 a minute. The patient became increasingly restless and suddenly stopped breathing. All efforts at resuscitation were without success and she was pronounced dead at 10:30 p. m., 30½ hr. after admission to the hospital.

Autopsy.—An autopsy was performed 15 hr. after death. The body was that of a well-nourished 31-year-old white woman. The lower extremities were of the same length, but the left thigh and leg were somewhat smaller than the right. The brain weighed 1,200 gm. and showed considerable edema and congestion. On section the brain stem revealed moderate injection. The spinal cord was markedly injected and edematous. Cross section of the cord in the cervical, thoracic and lumbar regions revealed moderate edema throughout. There were a few pin-point purple areas, most marked in the gray matter, but present also in the white matter. At some levels there was also loss of markings. In the lumbar region the left anterior horn was slightly smaller than the right.

The pleural cavities were free of fluid. The pericardial sac contained a few cubic centimeters of clear fluid. The larynx and trachea were free of fluid. The main bronchi contained a moderate amount of frothy fluid. The lungs were purple-gray, subcrepitant, and the posterior portions were congested. The cut surfaces everywhere were moderately moist with frothy fluid. The heart weighed 275 gm. It was soft and purple-gray and the valves showed no abnormality. Chambers of the heart were slightly dilated, and the coronary arteries had an occasional fatty plaque. The spleen weighed 200 gm. and was dark purple with follicles rather prominent. The liver weighed 2,000 gm. and was deep purple with no distinct markings. The kidneys weighed 300 gm. together and were dark purple-gray and congested. The stomach, pancreas, and adrenals showed nothing of significance. There was a 15-mm. gray nodule on the fundus uteri.

Degree of Involvement of the Nervous System As Shown by Microscopic Examination

	Parenchymatous	Interstitial	Vascular
Right frontal lobe	0	0	0
Left central ganglia	xxx	xx	xxx
Right dentate nucleus	0	x	x
Pons	x	xxx	xxx
Medulla	x	xxx	xxx
Cervical cord	xxx	xxx	xxx
Thoracic cord	xxx	xxx	xxx
Lumbar cord	xxxx	xxxx	xxxx

Microscopic examination of the cerebral cortex showed marked congestion of the overlying meninges. The cells and layers of the cortex were essentially normal. The central ganglia showed marked engorgement throughout. There was a large focal extravasation of blood near the left lateral ventricle. About this area there was marked diffuse infiltration of round cells and leucocytes, and many of the ganglion cells had disappeared or exhibited moderate neuronophagia. Most of the vessels were surrounded by round cells. The dentate nuclei of the cerebellum showed slight engorgement. The ganglion cells appeared intact. There was slight diffuse infiltration of round cells and leucocytes. A few of the vessels had small collars of round cells. The pons and medulla showed marked engorgement. Most of the ganglion cells appeared intact. Throughout the tissue there was moderate diffuse infiltration of round cells and a few focal collections of leucocytes. Most of the vessels were surrounded by collars of round cells. There was marked congestion of the entire spinal cord and meninges. The cervical and thoracic cord were notable for the disappearance of most of the ganglion cells from the anterior horns. The gray matter exhibited marked diffuse infiltration of round cells and leucocytes, and the white matter also showed slight infiltration. Most of the vessels of the gray matter and some of the vessels of the white matter were surrounded by collars of round cells and leucocytes. Changes in the lumbar cord were more accentuated, especially on the left side. There were a few foamy cells present in the anterior horns. On the left it was noted there was an absence of ganglion cells. The few remaining ganglion cells on the right side exhibited marked satellitosis and neuronophagia, and a few showed myelinization. Collections of round cells were prominent about the posterior roots.

The heart showed moderate interstitial edema, and the cross striations were indistinct. The splenic pulp was markedly engorged, and the follicles were large and lymphocytic. The liver sinusoids were engorged. The liver cells were swollen and granular. Many of the Kupffer cells were edematous and had large vacuoles. The glomeruli of the kidneys were engorged. There was marked engorgement throughout the lungs.

Clinical and Pathological Observations.—As a consequence of the first attack of poliomyelitis, the patient had marked weakness of the left lower extremity with moderate atrophy. The nerves supplying these groups of muscles had their origin chiefly in the lumbar region of the cord. Thus one would expect to find evidence of past pathology in this area. This was precisely the case. There was moderate atrophy of the left anterior horn of the lumbar cord, and microscopic examination revealed extensive destruction of the nerve cells. The pathological changes as a result of the second attack were very widespread and have already been discussed in detail.

COMMENT

Many second attacks of poliomyelitis undoubtedly have occurred which either passed unrecognized, or were not reported. But virus neutralization tests and studies of age incidence give strong evidence that at least some immunity to the virus of poliomyelitis is common. It is believed that adults are not ordinarily susceptible, because of acquired immunity following latent or subclinical infections. Failure to develop immunity from a previous attack is only characteristic of the exceptional person. Nevertheless, Fischer and Stillerman,[6] Nelson and Green,[7] and Bridge and others [2] reached the conclusion from hypothetical calculations that the incidence of second attacks of poliomyelitis is approximately the same as for recognized first attacks in the general population. This observation would indicate that no immunity against poliomyelitis develops following a primary attack of the disease.

The discrepancy in the two lines of thought might easily be explained by the existing evidence that there are different strains of the poliomyelitis virus.[8] It is therefore possible that second attacks of poliomyelitis may be produced by a strain immunologically different from that causing the first infection. Trask and others [9] showed that strains isolated from various outbreaks were not identical. Experimentally it has been found easier to reinfect monkeys with a different rather than with a similar strain of virus, although reinfection could be accomplished with an homologous strain.[10] During the last war, McAlpine [11] noted that the incidence of poliomyelitis for British and American troops was much higher among those stationed in India and the Middle East than for those in their home countries. He believed this difference might be explained by the fact that the foreign troops were exposed to a strain against which they had no previous immunity. Steigman and Sabin [12] have also presented strong evidence that immunity to poliomyelitis is specific for the strain of virus which caused the primary attack. Thus sufficient proof has been accumulated to lend credence to the idea that a second attack of poliomyelitis may be caused by an immunologically different strain.

Another consideration is that protection resulting from a first attack is relative. It is well known that individuals vary in their ability to produce antibodies and other defensive mechanisms against disease. In some instances, quantitative variations in the infectious agent may be the determining factor as to whether or not the disease will develop again after further exposure. At any rate, it is clear that in the management of poliomyelitis it is inadvisable to rely on a past history of the disease for certain protection against those who are acutely infected.

SUMMARY

A second attack of poliomyelitis with fatal termination and autopsy findings is presented. It is probable that this is the only reported authentic second attack with fatal outcome. Moreover, it is the first case recorded with complete pathological examination. On gross and microscopic examination the nervous system exemplified evidence of both recent and past pathology. It has been suggested that second attacks of poliomyelitis are due to an immuniologically different strain against which the patient has no previous immunity.

Medicine and Religion.—While the knowledge of early anatomy had been stimulated by embalming, practised for religious reasons, and by dissections, carried out in the search for omens in the pursuit of magic, the Greek Alcmaeon of Crotona, about 500 B. C., seems to have been among the first to perform, as a scientific observer, dissections and animal experimentation in the search for knowledge of anatomy and physiology. Medicine, in the earlier Greek civilization, clearly had origin in religion and was held to be a branch of philosophy. Later, medicine reached its zenith in the teachings of Hippocrates. Free from superstition, the Hippocratic school recognized in disease a process subject only to the laws of nature, and taught the natural history of disease as it is derived from accurate observation and careful interpretation of symptoms. Treatment was based on the fundamental concept that the healing power of nature was primary and the physician's responsibility was to further nature's ends—an influence which has extended over two millennia.—William A. Rogers, The Background of a Half-Century of Progress, *The Journal of Bone and Joint Surgery,* November 1950.

EPIDEMIC DIARRHEA IN A SCHOOL FOR BOYS

Theodore H. Ingalls, M.D., Boston
and
Commander Sidney A. Britten (MC), U. S. N.

In the latter half of October 1947 an explosive outbreak of nausea, vomiting and diarrhea affected 139 of 193 boys in a New England boarding school. None of the usual intestinal pathogens was identified. Evidence is presented that this kind of outbreak is no isolated event, and that the pattern of spread as determined from daily and four-hourly case incidence is more characteristic of a communicable disease transmitted by contact than of one caused by the ingestion of food or beverage.

St. Mark's boarding school is located in a rural area 25 miles from Boston and provides under one roof for the housing, feeding and instruction of 190 to 200 boys aged 12 to 18. The student body is subdivided into six forms (classes), which share common dining room, library, recreational and chapel facilities. The curriculum and daily routine are those of most college preparatory schools. About half the employees are residents of nearby villages and live at home; the others live on the school premises. Some faculty members reside in the various dormitories with the students, but the majority live in detached family dwellings near the main school building.

Within a period of 10 days 61 boys were admitted to the infirmary with various degrees of nausea, vomiting and diarrhea. Eighty others were treated as ambulatory patients or discovered by questionnaire. During this period, Oct. 17 to Oct. 27, 1947, symptoms referable to the gastrointestinal system developed in 141 (71 per cent) of 193 boys. In abruptness of onset, in attack rate and in progression through the school community the disease was much like that of pandemic influenza in the same school in 1917 (fig. 1).

THE CLINICAL DISEASE

Like the syndrome of nausea, vomiting and diarrhea described between 1935 and 1940 by Danish [1] and British [2] investigators and later by Reimann [3] and others [4] in the United States, illness was of less than 24 hours duration. Vomiting predominated in 31 per cent of patients, diarrhea in 22 per cent, while 40 per cent of the patients had both. The remaining 7 per cent had no more than mild manifestations of nausea or abdominal cramps. As analyzed by classes, the frequency and severity of symptoms were essentially the same for younger and older patients. Nausea and malaise sometimes antedated the vomiting by several hours, particularly during daytime. At night boys were often awakened by sudden and explosive vomiting. Diarrhea was copious, watery and free of mucus and blood. Stools commonly numbered from two to six in the course of a 12 hour period.

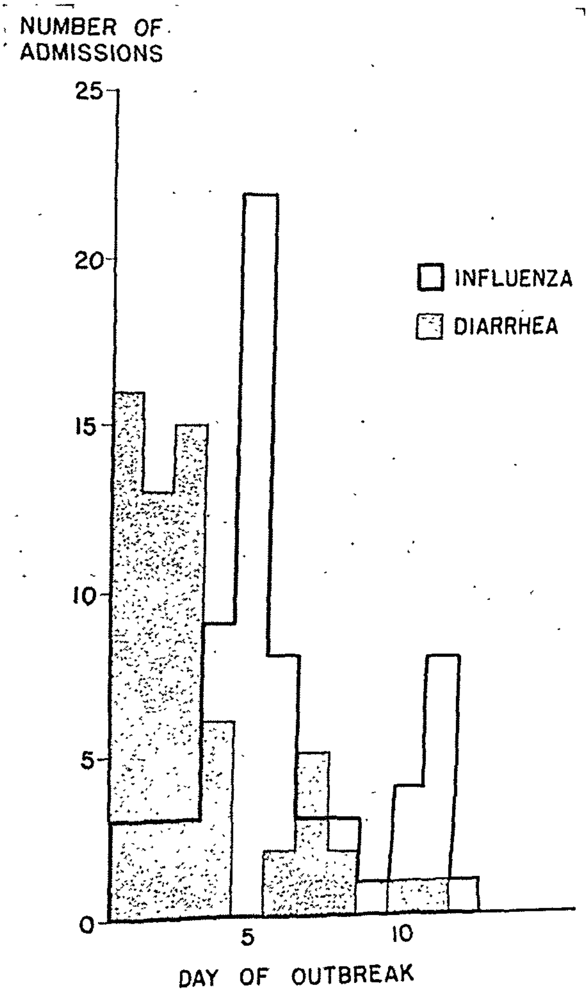

Fig. 1.—Daily admissions for the influenza epidemic of 1918 at St. Mark's school near Boston as compared with those for the diarrhea outbreak at the school in October 1947.

Although most patients were afebrile, approximately one-fourth had temperatures that ranged from 99 to 101 F. and averaged 100 F. Leukocytes in the blood of five sick boys ranged from 6,200 to 9,600 per cu. mm. Vomitus and stools were free of common enteric pathogens.

Recovery ordinarily was complete within 24 hours, and no boys remained in the hospital more than two days. Eight members of the football team, ill on Friday

night, were able to play most of the Saturday afternoon game—and to win. Active treatment was rarely necessary; for those committed to play football liberal ingestion of sugar-salt solutions was beneficial, and judicious handling on the field was necessary.

EPIDEMIOLOGY

The main part of the outbreak took place within a four day period, October 17 to 21, with a distribution of cases by four hour intervals as shown in figure 2. Primary and secondary peaks of incidence are shown to be 24 hours apart. Both occurred during the late night and early morning hours.

The data of tables 1 and 3 show a distribution of cases among members of form 3 (dormitory 5) that differs significantly from that of the school as a whole and from form 6 (dormitories 10 and 11), whether considered by form or dormitory assignment. The differing distributions shown graphically in figure 3 are inconsistent with mass infection spread from a common source, such as a common meal. The data support the concept of dissemination in this outbreak through personal contact.

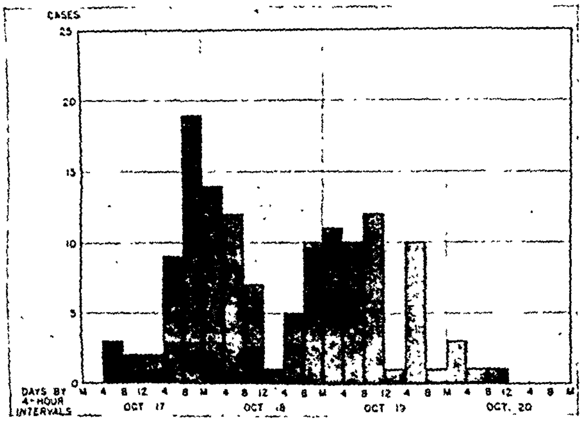

Fig. 2.—Distribution of cases by four hour intervals during the epidemic diarrhea outbreak at St. Mark's school in 1947.

Illnesses among employees and faculty and their families gave further evidence of contact dissemination. The hospital cleaning woman left the school at 11 a. m. October 17, vomited and had diarrhea at 6:10 p. m. Her adolescent daughter, who had not visited the school, awoke ill at 2 a. m. October 19. The interval was approximately 32 hours.

An instructor became ill at 5:30 a. m. October 18. His wife was ill at 8 a. m. October 21, and a son living at home became ill at 8 p. m. The intervals were 74 and 86 hours respectively.

Another instructor was ill at 6:30 a. m. October 18. A 10 year old girl who had come to visit the family on the previous afternoon became ill at 5 a. m. October 21. This was 70 hours after the onset of her host's illness and about 86 hours after arrival.

The school secretary's elder son, a student at the school, became ill at 9 a. m. October 20 and went home at about noon to remain through the following day. He was nursed by his mother who, in turn, had symptoms at 5 a. m. October 24, about 3½ days later. At 3:30 p. m. October 27 her youngest son, not a student at St. Mark's, became ill 82 hours after his mother.

EXPERIENCE OF OTHER SCHOOLS

That this kind of an outbreak is not an isolated event is suggested by correspondence with physicians of 20 other boarding schools in the northeastern United States. Twelve of them reported outbreaks of diarrheal disease between October 1947 and December 1948. The records of daily admissions, as shown in table 2, are similar to those at Saint Mark's, as were the clinical accounts and the lack of association of illness with an identifiable organism or common source of infection.

COMMENT

Explosive outbreaks of enteritis are always suspected of being caused by ingestion of food or water contaminated by a chemical or bacterial agent. This usually results in a tacit, if unproved, implication that the kitchen is at fault. With no relaxation of food preparation techniques or measures to assure purity of water and milk, good administrative control requires that gastroenteric illnesses not due to food handling are to be differentiated from those that are.

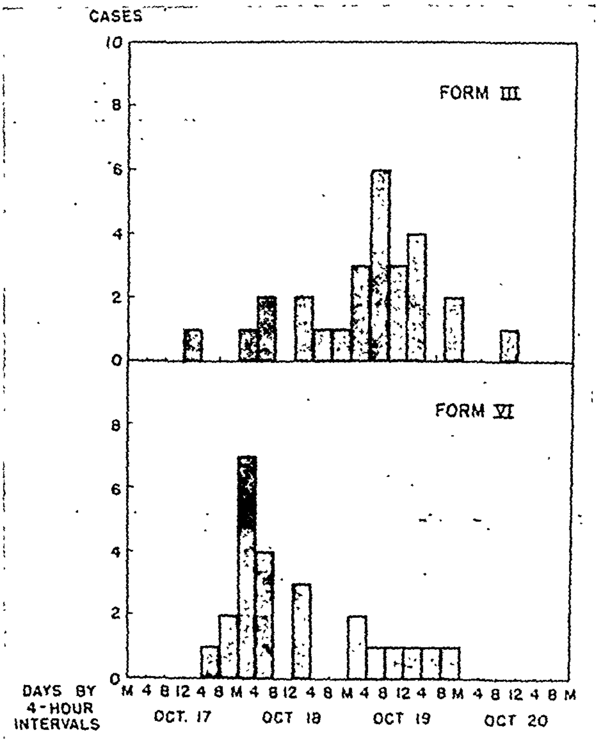

Fig. 3.—Distribution of diarrhea cases by four hour intervals in forms 3 and 6 during the school's four day outbreak.

The syndrome of *nausea, vomiting* and *diarrhea* described here is distinguished from food-borne outbreaks by epidemiological characteristics. As with influenza, clinical diagnosis of sporadic cases is impossible. Similar outbreaks have been described as occurring in nurseries,[5] in mental institutions [6] and in the general population.[7] Although there is no way of knowing whether the same etiological agents are at work, evidence that viruses are

involved has assumed prominence [8] as the severer enteric diseases of bacterial origin have come under control.

Within a closed community recognition of this illness depends on epidemiological observations and, in particular, the pattern of spread through the population. Due to its abrupt appearance, the large numbers involved and the shortness of its course, the usual recording of daily case incidence is likely to provide too coarse a scale. Arrangement of cases by four-hourly intervals served best, in this instance, to illustrate the pattern of spread. Search for ambulatory patients serves to indicate the extent and severity of the epidemic and to complete the pattern of spread.

* Data include ambulatory patients.

There is need for further investigation of cause, for at present it is impossible to prove or disprove the relation of one outbreak to another in different sections of the country and components of the populations or to recognize the sporadic case. Such recognition would be of more than academic interest should the highly fatal attacks of epidemic diarrhea that strike the newborn and the aged be due to the same biological agents as those of school children. This point is developed by Gordon and Rubenstein in their analysis of epidemic diarrhea of the newborn as a disease entity [9]: "The difficulty lies in lack of information as to whether infection is limited to the age group concerned or is more widely distributed in the population, perhaps manifesting itself in other clinical forms or as inapparent infection by reason of acquired resistance." Identification of the agent or agents and the development of a specific diagnostic test would be long steps toward clarification of the broad problem.

SUMMARY AND CONCLUSIONS

An outbreak of epidemic nausea, vomiting and diarrhea of unknown cause occurred at a boarding school for boys near Boston in October 1947. Clinically and epidemiologically it may be classified as that entity described by Danish and British investigators in 1935-1936 and later by Reimann and others. Analysis has been made of its behavior in a boarding school for 193 boys aged 12 to 18 and its spread to faculty families. The experience of 13 boarding schools with similar outbreaks has been summarized for 1947-1948.

Epidemic diarrhea among adolescent males is a distressing, but mild, short-lived disease disseminated by personal contact. Recognition early in an outbreak of enteric symptomatology will obviate the urgent sanitary measures required for food poisoning. The four hour case incidence record comprising ambulatory as well as hospitalized patients is a useful epidemiological procedure aiding recognition of the disease.

PERIODIC ARTHRALGIA IN TWENTY-THREE MEMBERS OF FIVE GENERATIONS OF A FAMILY

Hobart A. Reimann, M.D.
and
Angelo P. Angelides, M.D., Philadelphia

A disorder characterized by pain in the joints at regularly recurrent short intervals over many years with no other disturbances and without permanent disability has been recognized as an entity for over a century. Several reviews of the subject have been made.[1] It has been called hydrops genus intermittens, hydrops articulorum intermittens and intermittent hydrarthrosis. More recently the name periodic arthralgia has been used, because effusion into the joints is not always present and the disorder seems to be one member of a group of periodic disturbances. They are characterized respectively by regular recurrences of fever, abdominalgia, arthralgia, neutropenia, purpura and edema.[2]

More than 100 reports of cases of periodic arthralgia have been published, mostly in European journals. It is certain, however, that many more instances occur but are not discovered. Victims of the mildest form may never seek medical advice, or, because of its characteristic long duration, lack of disability or deformation and absence of other tangible evidence of disease, the disorder may be regarded as a neurosis. Patients in seeking relief may go from physician to physician so as to preclude prolonged observation and registration of clinical data, which bring to light its regular periodicity.

Periodic arthralgia is characterized by strikingly regular recurrences of pain and often swelling, usually of one or both knees, and of other joints of the extremities as well. In some instances only stiffness and in others effusion into the joint may be noted. The episodes usually recur at regular intervals of seven to 21 days, last several days, usually without fever or other symptoms or signs, and disappear until the next predictable bout. In some patients recurrences come at irregular short or long intervals. The disorder may begin at any time of life, and the intervals may shorten or lengthen. It may last a lifetime or may disappear either spontaneously or in rare instances after certain forms of therapy. Rarely do permanent injury to the joints and other effects on the general health occur. Biopsy study revealed edema of the synovial membrane with or without monocytic cell infiltration of the tissue.[3] Effusion of serous fluid, when present, may contain over 1,000 cells per cubic millimeter, and either polymorphonuclear cells or lymphocytes predominate.[1]

Our attention was called to the group of cases reported by a query published in THE JOURNAL requesting suggestions in regard to periodic pain in the extremities suffered by many members in five generations of a family (chart).[5] By the courtesy of Dr. F. R. Janney of Wauwatosa, Wis., two members of the family came to us for study. Ten others were interviewed at their homes in Chicago, and six living elsewhere replied to a questionnaire. Most of them had become accustomed to their periodic discomfort and, since it was not disabling or deforming, gave little attention to it. It was accepted stoically as a familial trait.

REPORT OF CASES

The following two patients, mother and daughter, came to the hospital for study.

CASE 1 (IV-13).[6]—Mrs. E. S., age 32, had pains in her joints since she was 6 months old. They recurred two or three times a week and affected the large joints of her extremities singly, in various combinations or all at once. The pain appears suddenly and may be dull or severe for five to 30 minutes. In a single episode there may be only one or as many as 20 bouts of pain, followed by three or four days of freedom from discomfort. The joints are always normal in appearance and nonpainful on motion. No other symptoms or signs occur except an urge to defecate during an episode, and occasionally immediate relief of pain is obtained after defecation. It was stated that with advancing age the frequency of the episodes had diminished to three in a month. Episodes of arthralgia continued unchanged during pregnancy. She bruises easily. Her past history is irrelevant except for urticaria four years ago. Physical examination revealed no abnormalities except for a few old ecchymotic areas on the right thigh and leg.

Laboratory Studies.—The blood count, sternal marrow and urinalysis showed no abnormalities. The bleeding time, clot retraction and clotting time were normal. The following measurements were made on the blood: uric acid, 1.9 mg., sugar 80 mg., calcium 10 mg., phosphorous 3 mg., urea nitrogen 9 and 19 mg., bilirubin 0.5 mg., total protein 7.4 mg., albumin, 5.9 Gm. and globulin 1.5 mg. The sedimentation rate (Cutler method) was 9 mm. in one hour. The result of urea clearance test was 57 per cent. A basal metabolic rate registered —1. The quantitative urine gonadotrophins were less than 6 units on three tests, the urine estrogens were 132 and 64 rat units and the 17-ketosteroids 3.6, 5 and 4.4 mg. A stain of a vaginal smear by Shorr's technic showed a slight to moderate estrogenic effect. Roentgenograms

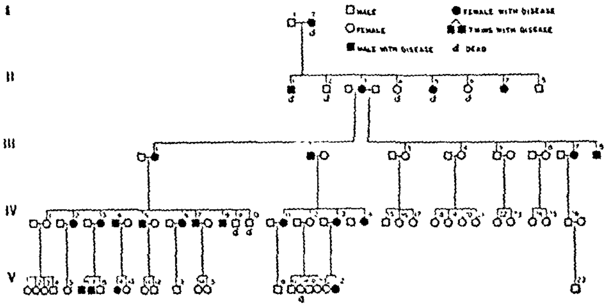

Chart showing periodic arthralgia in five generations of one family.

[6] The cases presented are numbered to correspond with the patients' places in the genealogical chart and in the table. The Roman numbers indicate a generation; the arabic ones, the respective members of it.

of the chest and extremities showed no abnormalities. An eight lead record in an electroencephalogram was a normal one. An epinephrine tolerance test gave a normal result; the absolute eosinophil count before injection was 203, and three hours after injection of 0.5 cc. of a 1 to 1,000 solution of epinephrine hydrochloride it was 44.

On the evening of admission, Oct. 4, 1949, the patient had two attacks of pain in both elbow and wrist regions and the left knee. Each lasted about 10 minutes. On October 5 there was severe pain in the left knee and ankle, which lasted for 20 minutes. The patient was observed at this time, but nothing unusual was noticed. She was then free of arthralgia until October 7, when a dull, steady ache developed in her left knee for about two hours. On October 10 she had four bouts of pain in the right elbow and wrist. On October 11 there were two short attacks of pain in the right knee and in the left elbow. On October 13 the finger and wrist joints were affected. The pain shifted from joint to joint and up and down the left arm for approximately one hour. Tripelennamine (pyribenzamine®) hydrochloride, 50 mg., was given, after which the patient had itching of the legs and chilly sensations and felt weak. Within an hour afterward the pain disappeared. It was the patient's impression that tripelennamine hydrochloride was not so effective as acetylsalicylic acid (aspirin) in providing relief from pain. The patient returned to her home with the request to register her attacks for two months. Although the episodes were said to occur three times a month, the record showed five episodes in October, one extending over four days, and seven in November, occurring at intervals of six, two, four, four, four and three days.

Case 2 (V-22).—R. S., aged 5, is the daughter of E. S., case 1 (IV-13), who stated that arthralgia began at the age of 6 months. The pain recurred four or five times a week but became less frequent, appearing now two or three times a week. The arthralgic symptoms are so similar to those of the mother that detailed description is unnecessary. They are occasionally so severe as to wake the patient from sleep. However, certain differences occur in this patient as compared to all other affected members of the family: there is occasional sudden flushing of the cheeks before the onset of pain, or during severe attacks red blotches appear on the face, and abdominal pain occasionally accompanies the arthralgic episodes.

Examination revealed no abnormalities except a few brown spots of resolving ecchymoses on the legs and arms. The same laboratory studies were made as were done of the mother, and no abnormalities were revealed except in the bleeding time, which was more than 10 minutes in two tests. An eight lead sleep-record electroencephalogram showed a focus involving electrodes no. 15 and to a lesser extent nos. 13 and 14. It was thought to be the result of trauma sustained at birth.

During hospitalization arthralgia occurred in various joints, including the toes and fingers, in various combinations but usually in the left knee and sometimes in the toes alone. Recurrences were so frequent that only one to three-day intervals of freedom from pain were enjoyed. Pain lasted five to 25 minutes and was often severe enough to cause the child to cry. In a few episodes the face was flushed, and in others small urticarial welts appeared on the forehead. Acetylsalicylic acid relieved the pain, but tripelenamine hydrochloride had no effect.

The following patients were observed at their homes.

Case 3 (III-1).—Mrs. M. H., aged 61, had 10 children, two of whom died at ages 1½ and 6 years, and neither had pains in the joints. Of eight living children, seven have periodic arthralgia; four are males, three females.

Mrs. M. H. was told that her episodes began in infancy, and she remembers them after the age of 5. They recurred three or four times a week but gradually came at longer intervals of once or twice a week and finally about once a month. The pains decreased in intensity with age and vanished a year after menopause began at age 47.

Arthralgia would appear in any large joint of the extremities, severe enough at times to wake her from sleep. The small joints were never affected. One or several joints were involved simultaneously or in succession. Pain usually lasted about 30 minutes. Black and blue spots appeared in the skin around the affected joint 24 hours later. No swelling, redness or heat were ever noted. The severity of any episode had no influence on the length of the interval before the next one. Acetylsalicylic acid and massage relieved the pain. Pregnancy had no influence on the recurrence or severity of the episodes. The patient began to have asthma at age 43, which persists. She bruises easily.

Her first child, now aged 40, and this daughter's four children have no arthralgia.

Case 4 (IV-2).—Mrs. E. F., aged 38, was told that arthralgia began at 6 months of age and recurred once or twice a week. The episodes gradually diminished in intensity and in frequency in the third decade, averaging once or twice a month. Ecchymoses appeared in the skin over the painful joints in childhood. As in case 3 (III-1) the same joints were affected singly or in combination in an episode. Attacks continued during pregnancy. She bruises easily. Her child, aged 1, is free from arthralgia.

Case 5 (IV-3).—In Mrs. E. M., aged 36, pains also began at 6 months of age, recurring two to three times a week. The periodicity lengthened after the onset of menstruation to once or twice a month. At age 16, an attack of jaundice lasting a month did not influence the nature of the episodes. The arthralgic episodes are identical with those in case 3 (III-1) and last five to 60 minutes. The pain feels as though something were boring out of the bone. In youth, black and blue spots occurred around the affected joints in severe episodes. As in case 1 (IV-13), an urge to defecate occasionally occurs during an episode followed by relief from pain. She is occasionally wakened from sleep by pain. Episodes recurred unchanged during three pregnancies. She bruises easily.

The patient's male twins, aged 5 (V-6 and V-7), both have arthralgia with black and blue spots recurring two or three times a week, first noted at 18 months of age. One twin has had asthma since the age of 18 months. Another son, aged 11 months, has had no arthralgia up to the present.

Case 6 (IV-4).—In Mr. A. H., aged 35, as in the others, pains developed at 6 months, which were most severe between 10 and 15 years of age. They recurred once or twice every two or three weeks. After age 19 the severity lessened, and the intervals lengthened to twice a year or less. Pains are not in the joints but in the mid forearm, mid calf and mid thigh regions and extend to but not into the nearest joint. The pain is boring and lasts 30 to 90 minutes. Pain may recur in the same areas in one episode.

The patient has two children; one, aged 5, is free from arthralgia, but in the daughter, D. H. (V-9), aged 6, pains began in early infancy. At first they recurred every two to three days, but now only once every two months. An episode lasted a day or two, then none appeared for two weeks, or three or four would recur on successive days. Attacks occurred day or night but usually at night, severe enough to wake the child and cause her to cry. In contrast with other relatives, pain is limited to her left leg. It appears, as in the father, in the mid portion of the tibia and radiates as far as the knee. No other joints ever are painful. No purpura occurs, but the skin bruises easily. Ecchymoses unassociated with trauma are usually present on the legs, but no other hemorrhagic tendency is obvious.

Case 7 (IV-5).—Mr. R. H., aged 32, has episodes that are like those of the others. Attacks of pain now recur once in two months, and purpuric spots appear around the involved joints. He is a dancer, and his legs are affected more severely than his arms. Neither of his two children, aged 2 and 6, have arthralgia.

Case 8 (IV-6).—Mrs. S. H., aged 28, has a history almost identical with those of case 4 (IV-2) and case 5 (IV-3). Her son, aged 7, has no pains.

Case 9 (IV-7).—In Mr. B. H., aged 26, pains were first noted at 6 months of age, recurring once or twice a week. In after years the frequency diminished to once a week, but the pain increased in intensity until age 21. Since then they recur once or twice a month. Pain is mild at first, reaches its worst in 10 minutes and lasts 15 to 60 minutes. It is relieved by acetylsalicylic acid. The elbows, wrists, knees and ankles are usually affected, and, in contrast with other relatives, the fingers and toes are occasionally painful. For about a year he has noticed that during the severest pains his hands and feet blanch and become cold for about 20 minutes. No ecchymoses occur, and he does not bruise easily. An episode leaves him feeling exhausted.

His two girls, age 4 months and 2 years, have no arthralgia.

CASE 10 (IV-8).—*In Mr. R. H., aged 19, attacks were noted at 6 months of age.* They recurred two or three times a week but have diminished to once a week. There may be several episodes over a period of a few days, then none for a week. The shoulder, elbow, knee, ankle and the metacarpal and metatarsal joints are affected in any combination or singly. For a period when he was approximately the age of 10, purpuric spots were noted around the affected joints. The same curious urge to defecate during the episodes and relief of pain thereafter occur as noted in other relatives. Acetylsalicylic acid also relieves the pain.

The following records of other afflicted family members were obtained on mailed questionnaires.

CASE 11 (II-3).—Mrs. M. B., the matriarch aged 86, had arthralgia beginning in childhood. For the past 30 years, pains have occurred less often and less severely. The characteristics of the episodes are similar to those in her descendants. Little is known about her mother (I-2) except that she had similar periodic arthralgia. The same is true of siblings II-1, II-5 and II-7.

Summary of Cases of Periodic Arthralgia

Case	Patient	Sex	Age, Yrs.	Age at Onset	Frequency at Onset	Later Frequency	Outcome	"Black and Blue Spots"	Remarks
1 (IV-13)	E. S.	F	32	6 mo.	2-3 X, wk.	Same	....	0	Urge to defecate, with relief; pregnancy no effect; urticaria
2 (V-22)	R. S.	F	5	6 mo.	4-5 X, wk.	2-3 X, wk.	....	0	Face flushes; abdominal pain; urticaria
3 (III-1)	M. H.	F	61	Infancy	3-4 X, wk.	1 X, mo.	Ceased, age 47	+	Pregnancy no effect; asthma
4 (IV-2)	E. F.	F	38	6 mo.	1-2 X, wk.	1-2 X, mo.	....	+	Pregnancy no effect
5 (IV-3)	E. M.	F	36	6 mo.	2-3 X, wk.	1-2 X, mo.	....	+	Pregnancy and jaundice no effect; urge to defecate, with relief
V-6 *	R. M.	M	5	18 mo	2-3 X, wk.	Same	....	+	....

6 (IV-4)	A. H.	M	35	6 mo.	1-2 X, 2-3 wk.	2 X, yr.	Less severe	0	Pain in thighs, calves and forearms
V-9 *	D. H.	F	6	6 mo.	2-3 X, wk.	1 X, 2 mo.	....	0	Left leg only
7 (IV-5)	R. H.	M	32	6 mo.	2-3 X, wk.	1 X, 2 mo.	....	+	....
8 (IV-6)	S. H.	F	28	6 mo.	1-2 X, wk.	2 X, mo.	....	+	Pregnancy no effect; urge to defecate
9 (IV-7)	B. H.	M	26	6 mo.	1-2 X, wk.	1-2 X, mo.	Less severe	0	Blanched hands and feet in episode
10 (IV-8)	R. H.	M	19	6 mo.	2-3 X, wk.	1 X, wk.	....	+	Urge to defecate, with relief
11 (II-3)	M. B.	F	86	Childhood	Unknown	Less	....	0	Duration of 80+ years
I-2 †	......	F	..	......	....	....	....	..	....
II-1 †	......	M	..	......	....	....	....	..	....
II-5 †	......	F	..	......	....	....	....	..	....
II-7 †	......	F	..	......	....	....	....	..	....
12 (III-2)	E. B.	M	58	Childhood	....	....	Ceased, age 16	0	Urge to defecate, with relief
13 (III-7)	F. A.	F	46	3 yrs.	1-3 X, wk.	Few times a year	Less severe	+	....
14 (III-8)	F. B.	M	44	Childhood	....	Less	Seldom in last 10 years	+	Pain in entire extremity
15 (IV-11)	E. S.	F	36	3 wks.	2-3 X, wk.	3 X, mo.	....	0	Pregnancy no effect
16 (IV-14)	D. N.	F	30	3 wks.	2-3 X, wk.	3 X, mo.	Less severe, not so often	0	Urge to defecate, with relief

* V-6 and V-7, children of E. M., case 5 (IV-3), and V-9, child of A. H., case 6 (IV-4), are not reported as separate cases in the text but are considered along with their respective parents.

† Nothing is known about these patients except that they had the disease.

CASE 12 (III-2).—In Mr. E. B., aged 58, arthralgia began in infancy and ceased at age 16. There was an urge to defecate in some episodes.

CASE 13 (III-7).—In Mrs. F. A., aged 46, pains started at age 3 or 4 and recurred several times a week for years. They have diminished in intensity and frequency and now appear a few times a year. Black and blue spots recurred for many years, but no relation to the arthralgia is stated in the questionnaire.

CASE 14 (III-8).—Episodes of arthralgia in Mr. F. B., aged 44, began in childhood but are lessening in frequency and severity. Pain seems to be not in the joints but in an entire limb. It may be precipitated by strenuous exercise. Black and blue spots occasionally appear on an affected extremity.

CASE 15 (IV-11).—In Mrs. E. S., aged 36, pains were said to have begun at the age of 3 weeks, coming two or three times a week. They gradually lessened in severity and came less often, at present about three times in a month. Arthralgia as in case 14 (III-8) can be induced by overexertion. The knees, ankles, shoulders, elbows and wrists are affected usually one at a time. In youth, all would at times be involved at once. Pregnancy did not influence the episodes.

CASE 16 (IV-14).—In Mrs. D. N., aged 30, pains were said to have started at the age of 3 weeks. They are similar to those of other victims and are now less frequent and less severe. There is often an urge to defecate during the episodes.

COMMENT

A group of 23 instances of periodic arthralgia as a dominant, nonsex-linked, hereditary trait in five generations of a family is described (chart and table). Evidence of heredity seems to be rare in periodic arthralgia and has been reported in only three other instances.[7] Many examples of hereditary periodic edema (angioneurotic edema), however, have been reported in several groups of four or five generations of families.[8] The disorder in the family described here is strikingly uniform in its behavior and began in early infancy in most victims. Among 19 members from whom information was obtained it lasted for life in many, about 80 years in one and lessened in frequency and severity in most of them. Nine bruised easily, but no abnormalities in the blood were discovered to account for it.

The occurrence of hemorrhagic spots raises the question of Schönlein's purpura with arthralgia (peliosis rheumatica),[9] which usually is grouped with Henoch's purpura (purpura with abdominalgia) as a syndrome called anaphylactoid purpura. Both arthralgia and abdominal pain were present in each of four of Henoch's original patients,[10] but apparently no attention was paid to his observation that the disorder characteristically comes in attacks at intervals of eight days or more. The curious urge to defecate during the episodes in six of the patients here described and abdominal pain in case 2 (V-22) further suggest the relation of these disorders. The relation of anaphylactoid purpura to angioneurotic edema was suggested by Osler. Schlesinger noted the resemblance of angioneurotic edema to intermittent hydrarthrosis [7c] and these were grouped with Kahlmeter's allergic rheumatism, Solis-Cohen's angioneural arthrosis and Hench's palindromic rheumatism by Weber.[11] Reimann finally included them as forms of periodic disease, together with a variety of other regularly recurrent disorders like periodic fever, periodic abdominalgia and periodic neutropenia.[2] Favoring this arrangement are a similar temporal periodic regularity of the various entities and a degree of overlapping signs and symptoms among them, as if there were a unity of origin. For example, arthralgia may recur with episodes of periodic fever, periodic abdominalgia [12] or periodic neutropenia, and, as in this report, purpura and abdominal pain occasionally accompany periodic arthralgia. Each separate group may represent only a different manifestation of the same underlying cause, and the predominant feature gives the name to the respective form it takes.

The inclusion of gout as a member of the group of periodic diseases was suggested,[13] and indeed Grandidier in 1872 [14] described a case of intermittent arthralgia of the knee recurrent every 14 days for years in a man from a gouty family. Gout was regarded by His [15] as the cause of intermittent swelling of the joints, and angioneural arthrosis may be mistaken for gout.[16] However, gout is rarely mentioned in any of the other reported cases of periodic arthralgia, and apparently no one has registered regularly recurrent episodes of gout.

Several features of the disorder in members of the family herein described vary from the usual picture of periodic arthralgia. The episodes do not occur at punctually regular intervals; concurrent purpuric spots appear in many of the victims, and in two instances pain was in the arm or leg, not in the joints. Pregnancy had a striking effect in the relief of the symptoms in intermittent arthralgia,[17] but in the present series neither pregnancy in six patients or jaundice in one had any influence. Nevertheless, there are enough characteristics in common to warrant the inclusion of the disorder under the heading of periodic arthralgia.

The cause of periodic arthralgia is unknown, but allergy has been incriminated oftenest. In the family described here, asthma or urticaria were present in four members. Allergic features were also present in the arthralgic families described by Frenkel-Tissot [7b] and Schlesinger.[7c] Allergy indeed gives rise to the various symptoms and signs characteristic of all the periodic diseases listed except periodic neutropenia. Hypersensitivity may have been the cause in rare instances reported by others,[18] since the disorder disappeared after removal of an offending protein. However, in cases of periodic arthralgia or of anaphylactoid purpura, failure to discover evidence of hypersensitivity to any protein is a common experience.[19] Elimination diets and treatment with antihistaminic agents almost invariably fail to influence the disorder. It must be assumed, therefore, that "anaphylactoid" or allergic-like manifestations do not always indicate hypersensitivity to proteins, but may arise from other unknown causes. A vasomotor disturbance was suggested as the best explanation of the various clinical phenomena of periodic disease,[2] but it had already been suspected in 1880 by Seeligmüller (cited by Frenkel-Tissot),[7b] and in 1888 Fridenberg regarded periodic arthralgia as a neurosis of vasomotor origin.[17b] No one yet has offered a satisfactory explanation for the recurrences of the disorder over many decades.

SUMMARY

Periodic arthralgia affected 23 members of five generations of a family as a dominant hereditary trait. In one instance it has persisted for about 80 years. The disorder has the characteristics of the Schönlein-Henoch syndrome. Both probably are manifestations of the same underlying cause and represent variant forms of a group of periodic diseases. The cause of the condition and the reason for its long-continued recurrences are unknown, except that one may suppose the immediate cause to be a vasomotor disturbance, as suggested 70 years ago.

The Fate of Homografts.—Homotransplantation of human tissues has intrigued the medical profession almost since the beginning of our civilization. It was not idle curiosity that lured various investigators into this field but a desire to procure permanent survival of homografts, an accomplishment of great surgical importance. There are the fields of endocrinology, reconstructive surgery, orthopedics, plastic surgery and many others in which successful homotransplantation would open up new horizons in the treatment of deficiencies and defects. The reports in the literature on this subject have been conflicting. It is true that homografts take well and may remain viable for different period of time. Indeed, during the first few weeks homografts may be indistinguishable, grossly or histologically, from autografts. Most workers agree, however, that homografts do not survive permanently in the new host and sooner or later they disintegrate.—*Hamilton Baxter, M.D., and Martin A. Entin, M.D.*, Clinical Study of the Fate of Homografts in Man, *The American Journal of Surgery*, March 1951.

DERMATITIS FROM LOCAL ANESTHETICS

WITH A REVIEW OF ONE HUNDRED AND SEVEN CASES FROM THE LITERATURE

C. Guy Lane, M.D., Boston
and
Ralph Luikart II, M.D., Santa Barbara, Calif.

A localized dermatitis as a result of contact with a local anesthetic topically applied or a well generalized dermatitis as a result of becoming sensitized to the drug appears sufficiently often to warrant a review of the subject. Such an irritation almost always occurs because of a hypersensitiveness of the skin resulting from a previous contact to that particular local anesthetic. Among dentists, dermatitis of this type has appeared frequently on the hands and elsewhere from procaine (novocain®) often causing considerable disability before the causal factor was recognized. It is now a matter of common knowledge among dentists, and consequently comparatively few cases are reported in the literature at present.

Other cases of dermatitis are reported among users of ointments and creams containing local anesthetics, especially when used to relieve pruritus, and particularly in the presence of an already irritated skin. Such cases have been observed frequently by dermatologists since Mook's [1] report in 1920 but often are not reported in the literature. It is unfortunate that the interest and news value of many common medical problems may fall so low after a brief period when they flourish in the literature. Often reports on relatively common diseases appear so seldom in journals that one may conclude from the literature that the condition is relatively unusual. Both Fox [2] and Parkhurst [3] have expressed their surprise at the infrequency of reports on epidermal hypersensitivity reactions to local anesthetics when their occurrence is so relatively frequent. Thomas,[4] Howell [5] and Morris [6] have presented evidence as to the frequency and importance of these hypersensitivities.

The local reaction following the topical application of one of these preparations may appear only as redness and itching. Further application usually results in a gradual extension of the inflammation, with swelling, vesiculation, oozing, crusting and often marked discomfort. All too often, other areas appear as a result of the increase of the induced hypersensitiveness of the skin, with perhaps a merging of the patches to form a generalized dermatitis. The original condition for which the local anesthetic was applied is greatly exaggerated, and the convalescence is usually slow and protracted even with the most soothing treatment and careful handling of the individual patient. Such reactions may follow the application of any of these local anesthetics.

The various groups of substances have been reviewed with regard to cases reported in the literature since 1921, although in our opinion the number of cases reported here does not begin to indicate the total number of cases or the amount of disability from such applications. Over a period of years the list of substances used as local anesthetics has gradually increased and numerous names have been adopted for the many preparations having the characteristic of producing local anesthesia (table 1).

PROCAINE HYDROCHLORIDE

Thirty cases of procaine epidermal hypersensitivity appearing in the literature are presented in table 2.[7] Sixty-six per cent are confirmed by positive patch tests. After the first reports of one of us (C. G. L. in 1921) 53 per cent of the reported cases appeared in the following two years. It would seem that more than 47 per cent of the use of procaine and its epidermal reactions have taken place in the years 1923 to date. This suggests that the reporting of these cases was popular in 1921-1922, and that the reporting of reactions in the literature is a low index of the true incidence. In only six of these cases were patch tests with a limited number of substances done to determine collateral sensitivity. However, the wide reach of local anesthetic sensitivity in the procaine sensitive patient is sufficiently impressive in the cases studied to warrant caution.

Considering the great numbers of patients in which procaine inadvertently contacts the skin surface and the fact that 83 per cent of the reported cases appear in people who use it with great frequency (dentists and physicians), it appears that many exposures are required for a given person to develop procaine epidermal hypersensitivity reactions and that the condition is basically an occupational disease.

ORTHOFORM

Of the seventeen patients with epidermal hypersensitivity to orthoform (methyl *p*-amino-*m*-hydroxybenzoate, old orthoform) reported (table 3), only seven were given patch tests with new orthoform (methyl *m*-amino-*p*-hydroxybenzoate). All seven reacted positively to the new as well as the old orthoform. Schwarzschild had little

[7] Patients reacting to epinephrine or other drugs in some procaine solutions were not included here.

difficulty in sensitizing his twelve subjects,[8] suggesting that hypersensitivity to the repeated topical application of orthoform might be frequent. Eight of these subjects[8] also were given patch tests with ethyl aminobenzoate (benzocaine), cycloform® (isobutyl paraaminobenzoate) and propaesin (paraaminobenzoic acid propyl ester). Only one subject had a positive reaction, and this person reacted positively to all three. Apparently cross sensitization here is not likely but does occur.

BUTAMBEN (BUTESIN®) PICRATE

Fourteen cases of epidermal hypersensitivity to butamben (butesin®) picrate are listed in table 4. In reading the descriptions of the cases of Sulzberger and Wise,[9] Fox[2] and Jackson,[10] one is impressed by the severity and long duration in the cases described. Fox and Jackson both point out the marked generalized "sensitization" reactions which may occur, and Oliver[11] states, "In patients allergic to that material I have seen most amazing generalized toxic dermatitis develop after the use of butesin picrate on minor injuries, cases in which there was no possibility of toxic products at the site of the wound being responsible." Trinitrophenol (picric acid) is a component of butamben picrate. Sensitivity reactions in some cases to the latter compound is probably based on a trinitrophenol sensitivity. Jackson[10] has described three cases of trinitrophenol sensitivity.

TETRACAINE (PONTOCAINE®)

Fourteen cases of epidermal hypersensitivity to tetracaine are shown in table 5. Thomas[4] made patch tests on 201 endoscopy patients, finding 20 with plus or 2 + reactions and three with suggestive reactions. Felton[4] patch-tested 49 controls with 2 per cent tetracaine, finding two with plus reactions and six with plus-minus reactions. Considering the incidence of hypersensitivity as indicated by the patients of Thomas and the controls of Felton, here again the literature would appear to give a low index of the occurrence of sensitivity.

So far as the cases of external epidermal hypersensitivity are concerned, tetracaine hypersensitivity seems to occur chiefly in ophthalmologists and their patients. Additional cases of tetracaine hypersensitivity are reported by Gans,[12] Gebb,[13] Mannheimer,[14] Marx,[15] Rauh,[16] Reitsch[17] and Sander-Larsen.[18]

DIBUCAINE (NUPERCAINE®) HYDROCHLORIDE

In addition to 11 cases of epidermal hypersensitivity to dibucaine (nupercaine®) listed in table 6, two cases[19] of general dermatitis have been reported from the widespread topical use of dibucaine. This agent is one of the most commonly prescribed creams for the relief of itching and has resulted in many cases of dermatitis which have not found their way into the literature. Its use should be restricted.

ETHYL AMINOBENZOATE (BENZOCAINE)

Among the eight cases (table 7) of epidermal hypersensitivity to ethyl aminobenzoate (benzocaine) Schwarzschild[8] and Paillard[20] studied the problem of collateral hypersensitivity and found it uniformly when it was sought. Sulzberger[21] remarks, ". . . in particular all local anesthetic drugs, such as benzocaine (ethyl-aminobenzoate), while they may temporarily relieve pruritus by their effect on the terminal nerve endings, are relatively frequent sensitizers; and can often produce or aggravate a dermatitis."

BUTACAINE SULFATE (BUTYN®)

In three of the eight cases (table 8) of epidermal hypersensitivity to butacaine sulfate (butyn®) listed collateral sensitivity was looked for and found.

OTHER LOCAL ANESTHETICS

Nine cases (table 9) of hypersensitivity to other local anesthetics are reported. Novol is a proprietary preparation containing chiefly procaine, epinephrine and chlorobutanol (chloretone®). Cases of sensitivity to this agent were not included under procaine because in one the patch test to procaine was negative[22] and in the other slightly positive,[23] while the tests to novol were strongly positive in both. Tests for epinephrine and chlorobutanol were not reported individually, but appear to be possibilities. The lack of case reports of hypersensitivity to piperocaine (metycaine®) hydrochloride might be explained by the unusual difference in its structure from most other local anesthetics, but this explanation is certainly not applicable to larocaine.® Apothesine,® like larocaine® a procaine-type compound, has apparently fallen into disuse. Sedothyol (a butyl aminobenzoate preparation) is closely allied to ethyl aminobenzoate (benzocaine): both are well known offenders. Nestosyl is a preparation containing ethyl and butyl aminobenzoates.

DERMATITIS AMONG DENTISTS

In November 1947, the Council on Dental Therapeutics of the American Dental Association, as a part of its program of therapeutic investigation, began to compile a list of dentists who were sensitive to procaine, butethamine (monocaine®) butacaine and other drugs used in their practice with a view to possible prevention and rational treatment of occupational dermatitis among dentists.[24] By Oct. 1, 1948 the council had obtained the names of 742 dentists reported to be hypersensitive to one or more items used in their practice. The results of the survey suggest that perhaps as many as 700 more dentists who have symptoms have not reported to the council.

About 400 of the dentists responding appeared to have a dermatitis due to local anesthetics.[25] A further study of some members of this group has been reported by Laden and Wallace.[26] In these dentists the hypersensitizing factor was restricted to substances of the procaine group and was not present in local anesthetics which differed markedly from procaine in their nucleus or side chain. It was found that relief depended upon avoiding these procaine preparations and adopting substitutes in other groups. Further investigation of group specificity is needed to explain the relationships of these various agents.

In table 10 are listed the 39 cases of dermatitis from local anesthetics among dentists and physicians, indicating the occupational hazard in these groups. This table emphasizes the figures obtained in the survey among dentists of the American Dental Association referred to above.

COMMENT

Howell [5] has suggested a presentday suitable criterion for cases of contact dermatitis: (1) known exposure to substance; (2) eczematous reaction to patch test in harmless concentration, and (3) elimination of substance resulting in clearing of the skin. When the reaction of epidermal hypersensitivity appears it is typically that of dermatitis venenata, but in long-standing dermatitis, such as continued occupational use of procaine, the reaction presented may be dry, fissured, scaly, and keratotic.[27] The reaction of epidermal hypersensitivity to local anesthetics topically used is usually characterized by a period of delay or development of the reaction of sixteen to forty-eight hours,[9] but it may not appear for as much as 45 days [28] after a single patch test. The dermatitis may progress for as much as 20 days [9] after it makes its appearance. Schwarzschild,[8] using the local anesthetic orthoform, demonstrated that in over half of his human experimental subjects epidermal hypersensitivity could be produced by repeated epidermal applications. Even corneal ulcers have been reported to follow the use of drops containing procaine.[29]

The problem of localized epidermal hypersensitivity appears to have progressed to this point: Patients with positive patch tests have been shown only in specific instances to have negative mucous membrane tests,[30] negative intradermal and scratch tests,[30a] negative Prausnitz-Kustner reactions,[31] negative abdominal patch tests with positive forearm patch tests,[30b, c] and an increase in reaction at the site of a previous patch test.[30b, c] Schwarzschild [8] states that in three fourths of his human experimentally sensitized patients a sensitivity of the entire skin was produced from one circumscribed area. McAlpine [27c] presented four cases with a positive patch test in three of which there was a negative conjunctival reaction and in one a positive conjunctival reaction. Berens [27c] had three patients with a positive conjunctival reaction, of which two had a positive skin test and one a negative skin patch test. This problem resolves itself perhaps into an integration of the factors of (1) time,[9] period of refractoriness to sensitization, and period of incubation to sensitization; (2) route of exposure to the skin, local or hematogenous at one time, and (3) amount of substance absorbed and distributed, or held locally, or desquamated with the reaction. Knowledge of these items and further data on group sensitivity to local anesthetics would seem to require further experimental elucidation. Today one might say that the presence of an epidermal sensitivity in a given area may mean sensitivity in all cutaneous areas in a given patient and that a single individual may have a sensitivity to other members of a chemically related group of substances,[28] and for the practical practice of medicine these thoughts may best serve our purposes for the moment.

The frequency of occurrence of dermatitis associated with the local application of anesthetic agents emphasizes the very wide use of these preparations for the relief of cutaneous symptoms. A casual search reveals the fact that many firms have produced preparations for relief of these symptoms in much the same way as the antihistaminic preparations are being brought out today. In table 11 are indicated some of these many preparations containing local anesthetics for topical application. It would seem advisable that some sort of warning concerning possible sensitization should accompany such preparations when prescribed for local use.

SUMMARY

The paucity of case reports of the frequent sensitizers among the local anesthetic drugs is surprising. Such cases occur frequently. One hundred and seven cases of epidermal hypersensitivity to local anesthetics are reviewed. Seventy-eight cases, or 73 per cent, were confirmed by positive patch test. In decreasing order of case report frequency they are: procaine, orthoform, butamben (butesin®) picrate, tetracaine (pontocaine), dibucaine (nupercaine®), ethyl aminobenzoate (benzocaine), butacaine (butyn®), apothesine,® larocaine® and piperocaine (metycaine®). Collateral sensitivity among these similar organic compounds is not infrequent and may be wide. A recent survey of dentists indicates a rather high proportion of dentists who have become sensitized to local anesthetics. These agents are an occupational hazard. In considering the problem of possible localized epidermal hypersensitivity it seems sound for practical purposes to assume that such a localized sensitivity may mean generalized sensitivity in any given patient. It would seem unwise to dispense or prescribe a local anesthetic preparation for topical use without being alert for the occurrence of epidermal hypersensitivity at any time. Furthermore, a word of caution about the possibility of such sensitization should be issued in all advertising material which concerns these agents.

ABSTRACT OF DISCUSSION

Dr. Earl D. Osborne, Buffalo, N. Y.: Dr. Luikart's paper is timely in view of the rapid increase in the use of local anesthetics incorporated in proprietary preparations. I made an analysis of 200 cases of dermatitis venenata, to try to obtain an idea of the incidence of reaction to local anesthetics as well as to other medication. These figures are rough because, in many cases, it is impossible to pin down the cause to a single specific agent. About 40 to 50% of the cases of dermatitis venenata that come to the dermatologist's office are due to medication of one type or another; of this 40 to 50%, between 10 and 20% are due to local anesthetics. An interesting point is the interrelation of reaction between related chemical compounds and their specificity. While an individual who reacts to a chemical compound of one type is likely to react to another related chemical compound, that is not always true. In testing patients with chrome compounds, for instance, we have noted many times subjects who would react positively to patassium bichromate and negatively to chromic acid, and so on. There are many other similar examples. A person who has dermatitis due to one chemical compound, when exposed to these local anesthetics or poison ivy or some other plant, is four to five times as liable to development of another dermatitis from additional sensitization to other chemical compounds as is a person who has never had a dermatitis venenata. If one tests any series of patients presenting dermatitis venenata from any chemical compound, in addition to the positive test to the specific substance, if he does enough tests he will invariably find two or three other positive reactions to completely unrelated chemical compounds; hence it is impossible to make a hard and fast rule. An interesting phase of this problem has to do with recognition of difficult cases of dermatitis scattered helter-skelter on the body. Local anesthetics are chiefly used in local areas such as the anal area, for pruritus ani, the vulvar area, for pruritus vulvae, and occasionally a localized area such as for insect bites, and often there will be an exacerbation of a dermatitis in that area without causing the patient too much concern, and at the same time a dermatitis will appear on the eyelids from contact with the fingers, or elsewhere on the body, such as on the nail in nail lacquer dermatitis, the eyelids, the cheeks and neck, and other areas. In a series of cases we found quite a number of examples of the presenting symptom being a nondescript dermatitis that had eluded detection, at least as to the cause, for many weeks or months.

Dr. Donald M. Pillsbury, Philadelphia: I should like to discuss this problem from another angle—whether or not these preparations are effective in the relief of itching. A fundamental error has been made in assuming that, because a preparation placed on the conjunctiva produces loss of sensitivity or because it produces anesthesia on injection, it will relieve itching on application to the skin. This whole problem has been under study by Dr. W. B. Shelley and others in our department for three years. Through the normal, unbroken skin it is impossible to get any anesthetic down to the nerve endings in a concentration sufficient to produce any relief of pain or itching. Shelley and others collected reports on some 57 different types of preparations that have been suggested for the relief of pruritus. In only two of those had the conditions of study been controlled at all. Those were both in the use of dibucaine. In one study it was thought that dibucaine was good, and in the other there was no demonstrable effect at all. If we can get a preparation which will relieve itching, or if there is even reasonable evidence that it will, one can possibly assume a small calculated risk of sensitization. But when we have this whole group of preparations in which there is undoubted evidence that they do produce sensitivity, that they do produce disability, and for which the evidence that they relieve itching is extremely slim, our position in the matter is poor. I think, therefore, that this report of Drs. Lane and Luikart is extremely timely.

Dr. Ralph Luikart II, Santa Barbara, Calif.: I am grateful to Drs. Osborne and Pillsbury for their reinforcement of the principle that we are trying to disseminate. Dr. Osborne wisely brought out the high percentage of incidence of these hypersensitivities. Collateral hypersensitivity to related compounds, as judged from collateral patch testing with similar organic chemicals in patients who are sensitive to local anesthetics, has indicated that the polysensitivity of a given person may be broad, particularly at the time of an acute episode. Often, after the acute episode is over, patch testing will reveal that the hypersensitivity appears then to be more chemically specific. I should like to add to one of Dr. Pillsbury's statements. Not only are local anesthetics dangerous, but frequently the prescribing of a local anesthetic in an ointment base (as is usually done) exaggerates the patient's pruritus. Do we occasionally overlook the fact that these ointment bases are physically occlusive in nature and the occlusion of the skin retains its local warmth, thereby increasing the sensation of pruritus? We should conclude, then, that not only may the topical application of local anesthetics be dangerous in many instances but also in individual patients their use in ointment form may increase pruritus.

Clinical Observations and Scientific Analysis.—Our knowledge of the nervous system has advanced enormously in the last half century, and the picture of its activity has changed dramatically from that of a static telephone system to that of a far more complex, flexible, mobile, dynamic instrument. This change has come about in good part because neurophysiologists have had to consider new phenomena, discovered in many cases in the clinic and by clinical workers, which demanded scientific analysis and interpretation. Such phenomena force the experimentalist and the scientific theoretician into broader and more useful and certainly truer views of the real mechanisms of the nervous system. The clinician who observes carefully and allows himself to think about the meaning of his observations will do a great service to medical science by supplying the experimentalist with valuable stimuli. This is nowhere better illustrated than by the clinical contributions in the field of pain.—R. W. Gerard, M.D., The Physiology of Pain: Abnormal Neuron States in Causalgia and Related Phenomena, *Anesthesiology,* January 1951.

THE SEXUAL PSYCHOPATH

Ben Karpman, M.D., Washington, D. C.

The general public has but a vague idea of what a sexual criminal is. It calls him a sex maniac, thinks he is some terrible monster, and is afraid of him. Questioned directly, women mention rape and perhaps exhibitionism or assaults, especially on children. The public is likely to regard simple molestation as of such little moment that in most cases it is not even reported. It accepts prostitution as an inescapable evil, shrugs in disgust at cases of homosexuality or perversion, and expresses profound disgust on learning of masturbation in public. The physician's attitude is hardly more enlightened. He treats the pervert (paraphiliac) with contempt and speaks of him as a degenerate, though the term carries a connotation of moral opprobrium that has no place in medical work. (The term paraphiliac is scientifically more correct and is more objective as well.)

The public has little idea of the meaning or frequency of sexual crimes or of their relation to the problem of crime in general. As a rule, people are indifferent to the problem. However, let some particularly revolting sexual crime take place, as rape followed by great abuse or murder, and the whole community becomes aroused, newspapers are filled with gruesome details, and the news of a sex crime wave spreads. A few sex offenders conveniently appear and are given heavier than usual sentences; the police redouble their energy in apprehending sexual offenders; the public spirit is appeased for a while, and the "wave" dies out. Actually it is doubtful whether there has ever been a real sex crime wave except, perhaps, during and shortly after a war, which generally favors a certain degree of moral looseness. It is also doubtful that the claim that sex crimes are on the increase can be substantiated by valid statistical reports. They are increased solely because of an increase in population but are not proportionately more numerous.

Laws are not clear as to the specific definition of sexual crimes. Sexual behavior that may be regarded as a felony and a crime in one jurisdiction is not considered even a misdemeanor in another. Furthermore, crimes obviously of a sexual nature and otherwise conforming to the original definition of sexual psychopathy (as, for instance, rape) are universally viewed by law as assaults, as offenses against persons. A person may commit incest in the privacy of his home and not fall within the definition of a sexual psychopath, yet be regarded and punished as such should the situation come to public attention.

With the exception of such clear-cut offenses as exhibitionism or assaults on minors, laws relating to punishment for sex crimes are far from specific. Technically, prostitution is a sex crime but is rarely punished unless something brings it to the attention of the public. Rape, clearly a sexual crime, is regarded by law as an assault on a person. One person convicted of rape may receive the death penalty, while in another jurisdiction and in circumstances that appear identical the charge may be less and the penalty not as severe. People have been arrested for carrying in their pockets pictures of nude men and women that differ in no wise from pictures published in nudist magazines, many of which are allowed to go through postal channels.

THE NOSOLOGICAL POSITION OF SEXUAL PSYCHOPATHY WITHIN THE FRAMEWORK OF NEUROSIS

The terms "sexual psychopath" and "sexual psychopathy" have no legitimate place in psychiatric nosology or dynamic classification. They are popularly and legally used to designate a certain type of behavior that, on the one hand, is characterized by socially prohibited or unacceptable sexual aggressiveness, and, on the other hand, by lack of regard for the feelings of the partner who is forced against his or her will to participate. Whether it is comparatively mild as in the case of simple assault, or whether it is severely aggravated assault, it is, as a rule, an expression of an uncontrollable urge, committed without logic or rationale, under the influence of a strong, overpowering drive. The act apparently gives no emotional satisfaction but only relief from unbearable tension. Such behavior represents practices that are not considered normal by the particular social order in which the person lives. As such, it clearly comes within the purview of the law, for by violating the morals or sexual independence of others it violates one of the basic principles of individual freedom.

The law regards these reactions as willfully perpetrated offenses, the results of malicious intent and premeditation. Psychiatry (more specifically, dynamic psychiatry), because of the opportunity it has had to study the deeper motivations behind human behavior, takes a broader view. It recognizes these reactions as part of a large group of behavior disorders commonly classified under the heading of perversions, or paraphilias (the paraphiliac neuroses). These are reactions that are not desirable biologically or culturally and are therefore prohibited. Homosexuality and related behavior are included here because biologically no issue can result from a homosexual union. The cultural paraphilias are those such as incest, pedophilia, and rape, which biologically can result in issue, though such issue is prohibited by our culture.

The definition of sexual psychopathy encompasses such behavior as exhibitionism, peeping, transvestism, masturbation, obscenity, and the like if committed in public but excludes the same reactions if committed privately. Thus, if one person forces another person under threat into homosexual activity, it is regarded legally as a sexual offense. However, if two persons by mutual consent engage in the privacy of their homes in homosexual relations, such behavior is not commonly regarded as sexually psychopathic. The laws of some states, however, classify such behavior as criminal and

Chief Psychotherapist, Saint Elizabeths Hospital.

Read before the Washington Society for the Advancement of Psychotherapy, April 21, 1950; the Maryland State Hospital Staff Conference, April 27, 1950, and the Medical Society of Saint Elizabeths Hospital, June 3, 1950.

punishable by statute. Some psychiatrists, too, appear to go beyond the ordinary definition and include any aberrant sexual activity as psychopathic. Thus, it has happened that a soldier or a sailor who in the course of a routine psychiatric examination admitted homosexual activities, though these were never committed in public nor came to public attention, was nonetheless given the diagnosis of "sexual psychopathy" and an undesirable discharge.

Meaning of the Paraphiliac Neuroses.—Dynamic psychiatry sees in paraphilias profound disturbances in the sex life of the person and patterns of sexual behavior not directed ultimately toward procreation, the goal of all normal sex life. The paraphiliac has not matured sexually, having failed to integrate his sexual needs and activities in such a way as to accord with socially accepted modes of sexual expression. He represents a kind of sex life that at an early period of development lost its normal goal, or rather, never having reached it, detoured into aberrant channels leading to an abortive aim-inhibited sexual activity. The latter, it often turns out, is but a substitute and a symbol for an originally prohibited sexual goal (e.g., incest). Nonetheless, the behavior is most persistent because it is so close to the instinctive. For that reason also it has lost nothing of its original strength; indeed, it is stronger than the normal sexual instinct, for less repression has been interposed in its way of expression. People suffering from paraphiliac neuroses are driven compulsively to seek gratification of an apparently insatiable urge.

Often patients come to psychiatrists for treatment of the general neurotic manifestations, such as anxiety or depression, suicidal trends, or psychosomatic disorders. The anamnesis, however, reveals overt homosexual behavior. The paraphiliac neuroses, though clinically seeming to stand apart, are in reality, in terms of psychogenesis, closely related to hysterical and other neuroses. They differ in that certain sexual trends, which in other neuroses find expression only in dreams and fantasies or perhaps some vicarious and cryptic sexual behavior, have become established in the paraphilias as fixed modes of behavior.

The majority of psychiatrists today speak of these reactions as psychopathic. One of the chief reasons that psychiatrists as a group have failed to recognize the basically psychoneurotic character of the paraphilias is that in these cases the practice of the perversion appears to be the most conspicuous characteristic and activity, as if the practice had absorbed the underlying neurotic symptomatology. Neuroses in general have a certain fluidity and mobility about them, the picture changing kaleidoscopically; the paraphilias, in contrast, impress one with a rigidity, an immutability, as if the reaction has become a permanent, fixed, and unchangeable pattern. A fuller study, however, reveals that behind the overt paraphilia there is a full-fledged neurosis. Here is a person who may be regarded as polymorphously perverse. There is hardly a paraphilia that he has missed. But the observer also finds in him a history of states of depression, inferiority feelings, hypochondriasis, hysterical convulsions, and the like. Another person is arrested on a charge of exhibitionism, but further study reveals a history of temper tantrums, inferiority feelings with strong compensatory drives, distinct sadomasochistic trends, and suicidal tendencies. An absolute homosexual, whose most conspicuous behavior is homosexuality, also suffers from hypochondriasis, syphilophobia, anxiety states, suicidal trends, somnambulism, inferiority feelings, and the like.

Sexual Psychopathy in Relation to Paraphilias.—While many of these reactions remain generally within the control of the individual, a certain group becomes detached from the general stream and assumes an antisocial character. That is to say, the sexual offenses are but an offshoot of the larger group, the paraphiliac neuroses. For the most part, the difference between the paraphiliac neuroses that are so well controlled by the individual as to keep him out of reach of the law and those of the so-called sexual psychopath, whose behavior is regarded as antisocial and criminal, is a difference only in degree rather than in kind. Exceptionally, it may be a difference in kind as well, as in the case of rape where the factor of violence is a necessary part of the picture; or in cases of transvestism where a person craves to be admired as a member of the opposite sex, or in exhibitionism where the sadistic element, the need that the other person be shocked and the consciousness that he is shocked, enters as a strong factor.

Yet similar reactions in an attenuated form occur privately among many people, both normal and neurotic. Some men can be aroused to greater potency if they violate the decency of a woman and shock her morals, even if she is otherwise a willing partner. Likewise, many men in the privacy of their homes will strut before a woman, hoping and wishing to be admired, or will expect the woman to behave in like manner; these are reactions of exhibitionism and voyeurism, respectively.

Two striking differences, however, must be noted between the ordinary paraphiliac neuroses and those that become antisocial. In the former there is an emotional relationship between the people concerned, whereas in cases of sexual psychopathy such a relationship seems to be lacking. The relationship is more symbolic and less direct and personal. Furthermore, in the instance of the sexual psychopath guilt with reference to the commission of the offense as well as to the victim, or for that matter even to his fellow men, seems to be entirely lacking.

The sexual psychopath and the noncriminal paraphiliac stem from the same sources and develop along the same path, but somewhere in the course of their development their paths diverge. One remains within the confines of nonlegal violations of social conventions; the behavior of the other asumes a legally prohibited form. The divergence in the course of development is effected early in life, which explains why on the surface the two reactions look quite dissimilar. The social offense with which the sexual psychopath may be charged, be it minimal or highly aggravated, is at the most a compromise with or a symbol of a greater offense that has been completely repressed because it is so strongly prohibited socially—namely, incest and homosexuality. The sexual offense, therefore, extreme as it may appear to be, is committed in lieu of another greater crime.

In turn, the paraphilias differ from ordinary neuroses, forming a group of their own—namely, the paraphiliac neurosis, which is as clear and distinct as neurosis (psychoneurosis) in general. Again, these two come from much the same sources, but, after developing in like manner for a while, their paths begin to diverge, one developing into psychoneurosis, the other into paraphiliac neurosis. Their divergence of paths is due to the fact that while one type of neurotic child, confronted with an emotional sexual problem, represses the prohibited sexual drive and converts it into psychosomatic or other emotional socially innocuous behavior such as anxiety or depression, the other fails to repress it and thinly disguised symbolic behavior results. In other words, while the neurotic converts his problem into psychosomatic and other types of socially acceptable though individually undesirable behavior, the paraphiliac neurotic converts his basic sexual problems into another form of behavior, which is socially nonpermissible but less so than that of the sexual psychopath.

It need not be supposed that all reactions and behavior of the neurotic, all his doings and all his thinking, are directly traceable to or can be accounted for by his neurosis. There are many areas in his life that are entirely comparable to those of the normal person. Though there are a few qualitative differences, for the most part his departures from the normal are on the quantitative side. Where the normal person confronted with a threatening situation may show some apprehension, the neurotic will over-react to it and show, instead, exaggerated anxiety. In a situation where a normal man may feel some resentment and express it by sarcasm, cynicism, scorn, or even biting wit, the neurotic will react with great anger, rage, or some antisocial, hostile act. Where a normal person confronted with the loss of a loved person will react with a depression that is relatively transitory, in the neurotic such mourning may develop into a long-lasting melancholia that far passes the bounds of the normal and may even lead to his death. Thus the neurotic is close to the normal; in a sense, it might be said there is some neurosis in everyone, and it is often but a question of degree of environmental strain as to how soon a person breaks down. Equally, there is something of the paraphiliac in every one of us and also something of the sexual psychopath.

The above consideration may seem strained and far-fetched, but there is a great deal of clinical truth in it, as is seen in the all-too-frequent instances where an apparently normal, previously well-adjusted person breaks down, and in whom a severe neurosis, a severe paraphilia, and perhaps acute sexual psychopathic behavior develop. Though most human beings react with disgust, even horror, rather than indifference to abnormal sex behavior, it is well to take cognizance of the fact that potentialities for it lie dormant in everyone. This consideration alone should make us adopt a more objective as well as a more tolerant attitude. Sexual psychopaths are, of course, a social menace, but they are not conscious agents deliberately and viciously perpetrating these acts; rather, they are victims of a disease from which many of them suffer more than their victims, often ending in the suicide of the sufferer.

Relation of Specific Paraphilias to Each Other.—Though when the structure of the paraphiliac neuroses is studied they are found to be closely interrelated psychogenically, by and large the paraphiliac indulgences, so far as society is concerned, are fairly pure culture products. Exhibitionists are rarely transvestists, though a minor exhibitionistic component may be found in transvestism. Likewise, the person given to obscenity will show in only a very remote sense such obvious sadistic trends as would bring him to the attention of the police, though a sadistic component may be discovered in the very fact or act of obscenity. A person given to compulsive raping is not likely to be exhibitionistic. Yet some overlapping does occur. Understandably, exhibitionism and voyeurism sometimes go together; they are mirror complements of each other.

Paraphilias and Psychopathy.—It can easily be seen how the term "psychopathy" came to be applied to this type of sexual offender. In both the sexual and the predatory psychopath there appears to be a lack of moral responsibility, selfishness, an inability to weigh and foresee the inevitable consequence of the particular behavior, difficulties in interpersonal relationships, and an uncontrolled aggressiveness. Yet on closer analysis the relationship between sexual psychopathy and predatory psychopathy appears to be rather remote, for the two proceed from somewhat different sources. It is extremely rare for a person charged with compulsive rape or fetishism to be found guilty of predatory exploits also. Occasionally this may happen, as when fetishism, for instance, goes with burglary; then it is discovered that the burglary was committed solely for the purpose of securing objects of fetishistic interest, e.g., female garments. Cases occur, however, where the two types of reactions are quite independent of each other, even if found in the same person, as in the instance of the exhibitionist who was also guilty of predatory exploits although the two reactions were not at all related, stemming from different sources.

To doubt the correctness of labeling these cases psychopathic is more than merely a question of semantics or conventional clinical diagnosis. These reactions, while admittedly antisocial, are basically neuroses of a particular, highly specific type. Nor can such behavior be regarded as an entity or disease in itself but only as a symptom-complex or syndrome; only as part of a complex, ramified neurosis, the paraphiliac neurosis. In its basic etiology, development, and formation, it differs in no wise from other psychogenic reactions, be they expressed as anxiety, compulsion, psychogenic asthma, or other neurotic symptoms; except that somewhere in its development, through a concatenation of specific situations, the neurotic conflict took a different direction.

CHIEF CHARACTERISTICS OF SEXUAL PSYCHOPATHY

Irresistible Character of Paraphiliac Offenses.—There is little doubt that the reactions that are attributed to sexual psychopaths are beyond the sphere of conscious or voluntary control and appear as irresistible impulses, which explains why in practice these cases do not profit by punishment; uncontrollable instinct is beyond any punishment. As neuroses, they have their specific causations, which may be of long-past origin that only at the moment has manifested itself by the particular sexual violation. Dynamic psychiatry views these reactions as neuroses, which in the fullest sense they are. It ascribes less importance to constitutional or immediate personal factors than it does to functional, deep-seated psychogenic emotional factors. For this reason, it has long attempted to cure sexual psychopaths in the same manner as it treats other neurotics. Amazingly enough, many such patients have responded to psychotherapy and actually improved and in some instances were entirely cured, when the specific etiology was uncovered and the person was given the opportunity to discharge the unhealthy and repressed emotions.

It has long been recognized that man's sex life differs from that of animals in being continuous rather than seasonal. Neurotics as a group have a stronger sex drive than the average normal person, and its strength may be expressed as satyriasis or excessive promiscuity; on the other hand, it may be diminished, because of many repressions, to the point of asceticism. The noncriminal paraphiliac appears to have a stronger sexual drive than the neurotic; the condition has become established and fixed; repressions do not operate here so efficiently as in neuroses. That this urge is never quite satisfied is apparent in the cases of many homosexuals who, after apparently satisfactory homosexual relations, masturbate, a reaction that does not obtain in normal persons. In the sexual psychopath the urge is much more compelling, so compelling indeed as to assume the character of a compulsive, insatiable, unremitting, unbridled (one might say inexorable), unrelenting drive that gives the man no rest or peace. It is not that the man, while he lives, also seeks sexual gratification, as is the case with the average person, but rather that he continuously has to have his particular sexual outlet in order to live at all. It is as if the man had consecrated his life to sex, which has become his most consuming interest; whatever other kind of life he leads appears to be purely incidental. There are exhibitionists who have exposed themselves several hundred times a day; I have recorded one case in which a man stood exposed in his window all day for all passersby to see. One voyeur would start each night at a particular apartment house and, armed with magnifying field glasses, look across at another apartment house to see what he could see, proceeding from one fire escape to another until he exhausted all the possibilities of that building; the next night it would be another apartment house, and so on. These people are all seeking an orgasm that must be attained at any price. It is well known that many sexual assaults, acts of exhibitionism, voyeurism, transvestism, sadomasochism, fetishism, and the like are preceded, accompanied, or followed by masturbation. In most if not all of them the individual's sexual drive has become a guiding force in his life; many order and organize their lives and living entirely within the framework of their particular drive.

Sexual Psychopathy and Nonsexual Crimes.—It is little appreciated that crimes with a sexual motivation are often hidden behind assaults that, on the surface at least, appear to be nonsexual. Aggravated assault and battery, assault with dangerous weapons, and murder often have a sexual motivation. This is seen in cases of rape followed by murder. Many criminals who violate the law in other than sexual ways fall essentially within the category of sexual offenders if basic motivation rather than superficial behavior is considered. In law, they are usually charged with felonious assault, mayhem, or murder. Here, as in the overt cases, the paramount goal is the securing of an orgasm. A young boy stabs a totally strange girl with a knife. Analysis reveals that he has a consummate hatred of women that must discharge itself in an act of aggression and hostility. His mind is continuously preoccupied with fantasies of the most cruel, sadistic torture. A man slashes the throats of young girls. On arrest, it is found that his underwear is bespattered with semen. To this group belong also the men who cut off women's hair, the acid-throwers, the fur coat and dress slashers, the Jack the Rippers, and the like. There are many pyromaniacs whose desire for an orgasm constitutes the sole reason for setting fires that have cost the lives of many people. This is also true of many kleptomaniacs. These are not so much sex crimes as crimes motivated by sex. But who can draw the thin and vanishing line that separates the two?

Distribution.—Sexual perversions (paraphilias) and sexual offenses draw no line in matters of race, class, or social position. There are homosexuals in the upper, middle, and lower classes. There are exhibitionists among white and among colored people. Such offenses occur among the highly intelligent as well as among the illiterate and the ignorant. Rousseau was an exhibitionist; Chevalier d'Eon was a transvestist; many gifted artists have been homosexuals. No age is immune, though each may have its particular type. The young adult may be exhibitionistic, while the man approaching senility may assault children, because he himself has come to feel much like a child (senile pedophilia).

Women are much less involved than men, though cases of women exhibitionists have been recorded as well as a few cases of female transvestists. Modern society permits larger outlet for women in some instances, as in transvestism. If a man dresses up as a woman it is an offense, but a woman may wear severely tailored clothes, ties, and short haircuts without exciting comment.

Relation to Normal Sex Life.—The sexual offense is not a substitute for normal sexual intercourse, and cases are known where neither excessive intercourse nor abstinence stopped it. It is a form of sexual activity all its own, satisfying some very specific needs of the individual that normal sexual activity cannot give. Contrary to popular misconception, people who read salacious literature are less likely to become sexual offenders than those who do not, for the reason that such reading often neutralizes what aberrant sexual interests they may have.

ETIOLOGY

Sexual offenses are no more hereditary than are neuroses in general. They are not due to bad sexual upbringing or to sexual ignorance. The development of perversions in general and sexual offenses in particular follows its own psychological laws, which are but little influenced by external situations. As an alcoholic man may come from a family of teetotalers, and a homosexual from a family of healthy sexual habits, so may a sexual offender come from a family with an unblemished moral background.

The fact is that as yet very little is known of the subject. The anatomy of the subject is hardly known; there is no specific statement of the types and conditions. Individual case reports are buried in the little-read pages of psychiatric magazines that rarely reach the attention of the general medical practitioner. No one has attempted to organize this diffuse material into something like a unit. As little is known of the anatomy, still less is known of its physiology—the physiogenesis, psychogenesis, and psychodynamics. General knowledge of the subject is in about the same state as general pathology was before Rokitansky and Virchow. Yet it is of vast importance, for its ramifications reach the most important aspects of our daily life. Sexual crimes bear a direct relationship to sexual psychopathology in general, and this to the psychopathology of neuroses.

A certain number of sexual crimes are committed by individuals suffering from brain diseases such as encephalitis lethargica, which argues strongly for the need of thorough physical examinations of all sexual (and other) offenders. Even these respond favorably to psychotherapeutic treatment. But beyond this, abnormal sex behavior, be it in the adult or the child, derives from the unwholesome family and social atmosphere in which the child develops. The fault lies with the parents, who, themselves products of unhealthy repression and much involved in sexual problems, do not know and cannot set themselves to be frank and open with the child whose naive and artless curiosity should have been handled in an equally simple way. Because of the many evasions, rationalizations, and sheer prohibitions, the child is led into aberrant channels that, not being corrected, become magnified and distorted. It is suggestive that sexual psychopaths do not come from families with psychopathic sexuality.

Most parents believe that not only are children ignorant of sex—which is not true of most children—but that they must remain ignorant, ignorance being equated with innocence. But where ignorance may be polluted knowledge, innocence may be good knowledge. Curiosity should be treated as a natural thing, not as a crime to be avoided or punished.

A good deal of the fault lies with the family physician, who sees many of these cases in the early stages of development. Even in these days of supposed enlightenment and sophistication there still seem to be many physicians who earnestly tell growing boys and girls that masturbation leads to insanity, body deterioration, and ultimate death. Harmless play such as "papa and mamma," "doctor and nurse," or "you show me what you have and I'll show you what I have," etc., is severely punished if discovered, which only creates an air of mystery and, therefore, attraction about it. At this stage many of the sexual problems are still latent and could be corrected with greater ease than years later. Instead, unreasonable prohibitions and proscriptions are imposed, with the result that they are driven underground, there to become withered and distorted.

TREATMENT

Legal Approach.—The law fails to prevent, correct, or deter sexual criminals from their activities; the problem must therefore be regarded as basically extralegal. There is no more need to have laws against perversive activities than there is to have laws against any illness, for such activities represent illnesses in the fullest sense of the word. This, however, requires a large amount of missionary work not only among physicians in general but even among psychiatrists. A great many psychiatrists still group paraphiliacs among those who are mentally abnormal though not insane, an invidious distinction harking back to the psychiatry of 50 years ago, which limited insanity only to psychoses. Dynamic psychiatry has gone far beyond that, becoming more inclusive and comprehensive, taking into its province all those reactions that, having pathological motivations behind them, lead to abnormal social behavior. Indeed, where is the difference between a schizophrenic who walks around naked because the voices told him to do so and the exhibitionist who, without hallucinations but through some obscure and irresistible inner urge, having no less force than hallucinations, feels driven to expose himself in public? So far as basic motivations are concerned, one is just as insane as the other. Where is the difference between one individual, shortly before fully oriented and seemingly normal, who is provoked into a rage leading to assault and murder, and the paranoiac with a history of long deliberation who seemingly in cold blood kills an innocent man who unfortunately happened to be part of his paranoid system? Objectively, the former would seem less guilty than the latter, for he certainly was not himself when in a rage. But it has been decreed that one is a neurotic and therefore not insane while the other is a psychotic and therefore, *ipso facto,* not responsible. In terms of underlying motivations, both had in them latently a surfeit of aggressive hostility that was brought to the surface by incidental situations. Just as the hallucinations of a schizophrenic or the delusions of a paranoiac cannot be destroyed merely by punishing the person, neither can the exhibitionistic urge be done away with by repeated punishment, or a smoldering hostility that leads to an unprovoked assault neutralized. Both reactions are beyond the conscious control of the person and are therefore removed from the sphere of personal responsibility.

In dealing with the problem of sanity and insanity the law has attempted to draw absolute and clear-cut distinctions that do not exist in reality and has shown an unwillingness to recognize distinctions and differences. In the eyes of the law the man is either sane or insane. Furthermore, the law has equated psychoses with insanity, leaving neuroses out of consideration. In many respects psychiatrists, mainly of the conventional, descriptive type, have subscribed to this. The fallacy of the approach is seen especially in the consideration of psychoses versus neuroses. It is true that psychotics who reach hospitalization are insane in the full sense of the word in that they have more or less lost touch with reality and are unable to take care of themselves. But there are many neuroses in which for all practical purposes the patient has lost touch with reality and requires hospitalization. They resemble psychoses so closely that the original distinction seems all but to have disappeared; indeed, many of them are diagnosed as psychoses; only prolonged hospitalization reveals lack of deterioration and merely invalidism.

The invidiousness of the distinction becomes obvious when the laws relating to sexual psychopaths are studied. The term is defined in the District of Columbia by Public Law 615, 80th Congress (approved June 9, 1948), under Title II, Section 201:

> The term "sexual psychopathy" means a person, not insane, who by a course of repeated misconduct in sexual matters has evidenced such lack of power to control his sexual impulses as to be dangerous to other persons because he is likely to attack or otherwise inflict injury, loss, pain, or other evil on the objects of his desire.

What sort of person, it may be asked, is it who is not to be regarded as insane yet whose repeated misconduct in sexual matters reveals an utter lack of power to control his impulses, an irresistible desire to attack other people without regard for social or personal considerations? Who does not know the paranoid schizophrenic who attacks innocent people and for this reason becomes dangerous to the community? Where is the difference between the sexual psychopath who impulsively attacks an unknown person, and the schizophrenic who does the same thing?

Psychiatric Approach.—Treatment of these conditions already exists, but its availability has hardly reached the profession. When a sexual psychopath comes to the attention of a physician the latter speaks of him as a pervert, a degenerate, to be treated wtih contempt. Most psychiatrists engaged in psychotherapy would rather treat 10 cases of anxiety neurosis than one of paraphilia. There appears to be a conviction among them that the only way to deal with these people is by means of law. But stricter laws, longer sentences, and bigger prisons will not solve the problem, for they do not cure the basic causations. Punishment has never been an effective deterrent in sexual crimes. There are exhibitionists and voyeurs who have served innumerable and long prison sentences without the slightest effect. Only a few centuries ago homosexuals and paraphiliacs were executed on the gallows. If all sexual psychopaths and paraphiliacs were exterminated today the next generation would have just as many as this. Available knowledge suggests that the causation of these reactions is extralegal and generally speaking extrasocial.

The proper treatment of the sexual psychopath is not confinement but psychotherapy, or, better yet, proper sexual education in childhood. But in order to know how to proceed with such education, it is first necessary to know more of the normal sexual development. Thus envisioned, the treatment of the sexual psychopath becomes a social problem in the fullest sense of the word.

PROPHYLAXIS

What is needed above all is prophylaxis, but of this there is as yet virtually nothing. Punishment has never proved to be the deterrent to predatory crime that it has been supposed and is even less so to sex crimes, which are related to situations that lie very close to the instinctive and have arisen early in life. An adequate prevention program should involve not merely sex education, or even education in general, but a complete reorientation of family attitudes with concomitant reconstruction of the training and development of children. To do that it would first be necessary to know more of the psychic genetic factors in the development of sex life. Such studies have only recently been begun, but enough material is available to make a good start.

The importance of studying sexual psychopathology cannot be overestimated. The ramifications of sexual psychopathy are deep and interpenetrating. It is intimately related on the one hand to general and other marginal antisocial behavior and criminality and on the other hand to mental diseases in the widest sense of the term. It goes hand in hand with prostitution, with alcoholism and drug addiction, and with psychoses and neuroses. There is no mental disease that is not involved deeply in the problem of sexual abnormalities, from the schizophrenic whose sex life dwindles down to abortive sex experimentations accompanied by excessive masturbation and not infrequently leading to pedophiliac assaults, through the manic with his seemingly exuberant but all too often deceptively weak sex life, his not very effective efforts at masturbation and other extrabiological experimentations, to the senile pedophiliac who, regressing to second childhood, resorts to sex play with children because of increasing impotence. There are some who believe that sexual pathology lies at the base of mental diseases and most emotional disturbances. In any event, it is an exceedingly important problem in life.

Every year perpetrators of rape and other sexual criminals are being executed or sentenced to long terms of imprisonment. Those who have been executed have carried the secret of their pathology with them. Those who are imprisoned are not being studied. The state gains nothing from a death sentence; society loses. The human psychopathologist has the same reaction toward this as a general pathologist would have were he continuously denied autopsy after autopsy with no opportunity to learn of the structure and function of disease processes. How far would medicine have advanced under such conditions?

There must be an organized formulation of disease. A concerted effort to study the structure and function of sexual aberrations is needed; for this the sexual psychopath provides the best subject. Teams of trained workers to search the records of courts to help learn of the various types of crimes and criminals should be provided; from this it should be possible to develop a workable, if only tentative, classification of the various subtypes within this grouping. An institute where cases could be studied in the fullest possible detail is also necessary. One year an attack might be made on the problem of exhibitionism, another year on pedophilia, still another year on rape, and the like.

But all such plans as proposed are chimerical overambitious dreams, not likely to be realized in the foreseeable future. It is easier to punish than to instruct, to effect discipline than to teach morale. The chance is, therefore, that stricter laws, bigger prisons, and stronger guards will be necessary, while the sexual psychopath will remain a very real member of society.

1801 I St. 6.

CLINICAL NOTES

PULMONARY SPIROCHETOSIS

Lieutenant Colonel R. W. Mendelson,
Medical Corps, United States Air Force

Castellani was the first to report on pulmonary spirochetosis, in 1906, and since then many case reports have appeared in the literature, chiefly from the Far East and also from Central and South America. It is generally accepted as a disease entity, although Manson-Bahr, David T. Smith and others doubt the etiological role of the spirochete. Whether or not the spirochetes found in cases of pulmonary spirochetosis are identical with those found in the buccal and pharyngeal cavities of normal persons is still a matter of debate in some circles.

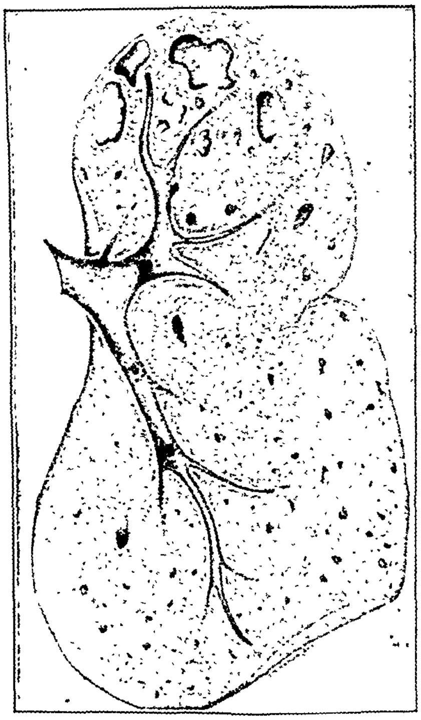

Fig. 1.—Cross section of lung showing cavitation in upper lobe.

The predominating organism in pulmonary spirochetosis is the Spirochaeta schaudinni. It is pleomorphic; the typical form presents a delicate spiral with many uniform coils, one end being blunt and the other pointed. It is stained easily with ordinary dyes and can be cultivated on artificial mediums. The fusiform bacilli found associated with the spirochetes probably represent a stage in the life cycle of the organism.

Clinically, the disease may be divided into acute and chronic forms, with manifestations indistinguishable from other acute or chronic pulmonary infections. The degree of clinical evidence is a matter of massive or mild infection and host resistance. There are no characteristic signs or symptoms to distinguish pulmonary spirochetosis from pulmonary tuberculosis, mycosis or other infections of the lungs. The roentgenographic changes are not distinctive and are not used as an aid in the differential diagnosis.

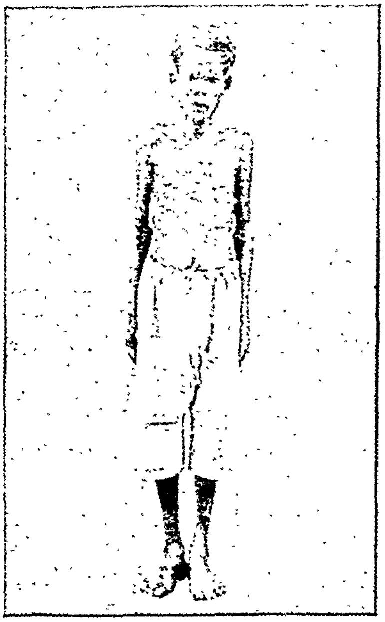

Fig. 2.—Patient with far advanced pulmonary spirochetosis.

I have observed the condition as a disease entity many times in the Orient, the diagnosis being established by the complete exclusion of other etiological factors, the production of pulmonary lesions in monkeys after intratracheal inoculation of infected material and the recovery of the organism in quantity from the lesions in the inoculated animals.

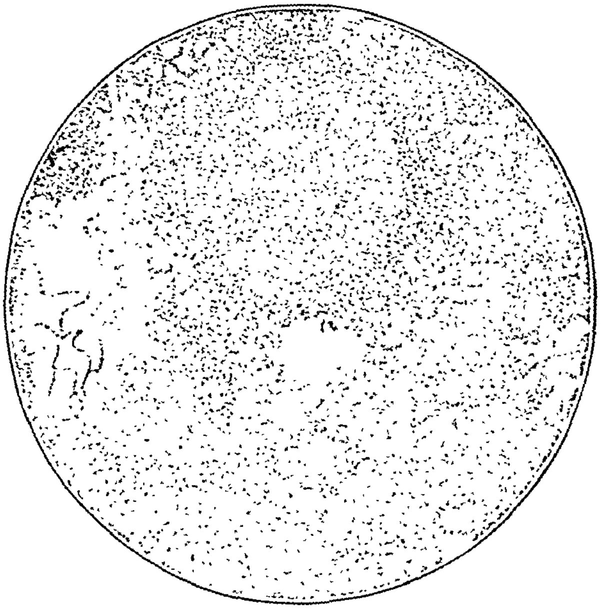

Fig. 3.—Microphotograph (low power) illustrating extensive necrosis of lung tissue.

The following case is one of far advanced infection.

REPORT OF A CASE

A 38 year old oriental applied for treatment, complaining of loss in weight, anorexia, bouts of fever, productive cough and hemoptysis. He had been ill a year and had taken a variety of native remedies, including such mixtures as powdered tigers' whiskers and claws and various native herbs, combined with the application of dung plasters to his chest.

Physical examination revealed a rather cadaverous person, with a pulmonary condition indicative of far advanced tuberculosis. The roentgenogram substantiated this diagnosis, but painstaking laboratory investigation, including inoculation of infected material into animals, failed to revealed an acid-fast organism. The sputum was frothy and pink, contained many S. schaudinni and was practically free of other organisms, with the exception of numerous fusiform bacilli and staphylococci. Intratracheal inoculation into monkeys resulted in active pulmonary lesions from which spirochetes were recovered, and reinoculation of the recovered material resulted in active disease in the lungs of previously healthy animals, from which the spirochete was also recovered. The patient died after a severe pulmonary hemorrhage, and the autopsy revealed extensive cavitation and parenchymal necrosis; proliferative lesions were not observed. No acid-fast organisms were recovered from the postmortem material, and inoculation of the same into animals was nonproductive of tuberculous lesions.

COMMENT

Although patients with pulmonary tuberculosis harbor at times spirochetes as saprophytes, extensive pathology may result from infection with S. schaudinni. Early diagnosis and treatment with arsenicals will cure the acute disease in practically all cases and arrest the moderately advanced in many, but fatal results are not unknown.

SPONTANEOUS CEREBROSPINAL RHINORRHEA WITH REMISSION FOLLOWING DYE INJECTION

Alfred Kahn Jr., M.D., Little Rock, Ark.

Spontaneous cerebrospinal rhinorrhea is a rare disease. Coleman and Troland[1] defined spontaneous or idiopathic rhinorrhea as the discharge of spinal fluid that occurs through the nose in the absence of (1) trauma to the head, (2) infections of the bones of the paranasal sinuses, (3) tumors eroding the base of the cranium, (4) prolonged increased cerebrospinal pressure, and (5) demonstrable congenital anomalies. They found only 12 cases in the literature since 1920, and only two additional cases were found in the literature by me. Cloward and Cunningham[2] reported one case, of four months in duration, affecting the left side. Surgical intervention was instituted, and the flow stopped. The other case, of nine months in duration, in which infection was the mode of onset, was reported by Love and Gay.[3] In this case, also, surgical intervention was instituted, and the flow stopped. Love and Gay reported two other cases but they do not seem to fulfill the above criteria.

Various explanations which have been offered as to the mode of escape of the cerebrospinal fluid have been reviewed: fluid escaping through remnants of the craniopharyngeal canal, a persistent olfactory ventricular lumen, holes in the cribiform plate, fluid escapes along the nerve sheath, and areas of the cribiform plate which are deprived of nerves.

The case reported here fulfills all the criteria of spontaneous cerebrospinal rhinorrhea. This case is of additional interest because the dye substance, indigo carmine, used in the diagnostic test may have been responsible for the cessation of the rhinorrhea.

REPORT OF CASE

History.—The patient, a 47 year old woman, stated that she had been completely well until 1947, when she first began to feel as though her throat were filling with liquid. There was no cough or sputum. A check by a local otolaryngologist disclosed some fluid collecting in the region of the larynx, but the source of the liquid was not identified. The moisture continued to collect, and the amount increased as time went by. In June, 1949, while she was bending over, a profuse clear discharge from the left nostril developed in the patient. This continued unabated, the liquid dripping from the anterior nares at the rate of about 1 fluid ounce (30 cc.) per hour. It was colorless, devoid of mucous, and had a salty taste. In August, 1949, the patient began having intermittent bouts of fever up to 100 F., which usually occurred in the morning about 9:00 and lasted from one to two hours. There were occasional chills with the fever. A chest x-ray, which was then taken, disclosed a cloudy infiltration in the left lower lung field.

The family history, habit history, social history, and past history were noncontributory. The patient denied injuries of the head, headaches, and signs and symptoms of intracranial tumor.

Physical Examination.—Physical examination found the patient's height to 5 ft. 6½ in. (169 cm.); weight, 180 lbs. (81.6 Kg.) and oral temperature, 99.2 F. The blood pressure reading was 138/78. The pulse was 80 a minute, and the respirations were 20. There was a watery, nonmucoid, clear, left nasal discharge amounting to 60 cc. an hour. The ears showed a minimal scarring of both drums. There was no adenopathy; the thyroid was not enlarged; the heart was normal, and lungs were clear. No masses were felt in the abdomen. The pelvic, skin, and neurological examinations were not remarkable.

X-Ray of the Skull.—A roentgenologic examination of the patient's cranium was made by Dr. D. A. Rhinehart. Left lateral stereoscopic x-rays of the entire skull and oblique stereoscopic x-rays from above downward and forward through the skull, the orbits, and the bones of the face were taken. The examination of the lateral roentgenograms showed nothing suggesting any cranial or intracranial disease. Examination of the oblique roentgenograms was noncontributory except for four cyst-like shadows in the left ethmoid region; these had no counterpart on the right.

Laboratory Studies.—The findings of the laboratory studies on the blood and the urine were essentially normal, and the stool was guaiac negative. Chemical analysis of the left nasal fluid revealed a protein content of 16.6 mg. per 100 cc., sugar, 58%; chlorides, 735 mg. per 100 cc., and rare epithelial and white blood cells.

As a special diagnostic test, 2 cc. of indigo carmine dye was injected by Dr. Robert Watson at the fourth lumbar interspace; shortly thereafter the dye appeared in the fluid from the nose.

Course.—The patient was hospitalized on Sept. 23, 1949, for the indigo carmine dye injection and was discharged later the same day. That afternoon the patient developed a severe headache, which continued throughout the following day. Through this period the drainage continued. It spontaneously ceased approximately 36 hours after the dye injection. Because of the severe headache, approximately 48 hours after the dye injection the patient was rehospitalized in a neighboring city. A diagnostic lumbar puncture was performed, and the rhinorrhea began again

and continued for several hours. The spinal fluid was negative. The only subsequent reappearance of the spinal fluid occurred after a second diagnostic lumbar puncture, five days after the readmission to the hospital; that drainage lasted less than one hour. The rhinorrhea has not recurred in more than one year.

COMMENT

This case fills all the criteria of a spontaneous idiopathic cerebrospinal rhinorrhea, as there was no history of trauma or infection, no demonstrable tumor, no increase in cerebrospinal fluid pressure, and no apparent congenital defect.

The cessation of the rhinorrhea is curious. No therapeutic measures were instigated. One might speculate as to whether or not the indigo carmine dye could have started an inflammatory reaction which eventually sealed off the meningeal defect. An alternate possibility is that, in performing the lumbar puncture, the pressure drop was sufficient to let bacteria into the defect; their proliferation might then cause sufficient tissue reaction to seal the leaking point.

The patient has had no further fever. The fever seemed to be related to the rhinorrhea, although it is not possible to say if this was due to infection at the site of the leak, or secondary to pulmonary infection from the constant drainage into the lungs.

Inasmuch as the rhinorrhea has not recurred, the consulting neurosurgeon advised against any operative intervention at this time. Since the patient has had no nasal drippage for approximately 12 months, it is possible that future surgery can be avoided.

SUMMARY

A case of spontaneous cerebrospinal rhinorrhea that fulfills the requirements suggested by Coleman and Troland, is reported.

The rhinorrhea stopped without surgical or medical intervention and has not recurred for 12 months.

The possibility that the dye substance injected (indigo carmine) or infection caused the rhinorrhea to stop is discussed.

ADDENDUM

On two occasions since the submission of this article, the patient has been given careful examinations without evidence of recurrence of the rhinorrhea. On May 14, 1951, without antecedent infection, exertion, or injury a slow discharge of spinal fluid recurred from the left nostril; this has continued to date.

Preventive Medicine.—The most important concept of the century in the field of medical care is the idea that preventive medicine is an integral and necessary part of the everyday practice of medicine. It is not a separate body of knowledge to be understood only by a skilled technician who has been highly trained in this field. There is no "specialty" of preventive medicine, as there is a specialty in surgery, radiology or pediatrics. There is, of course, a specialty of public health, which is a well organized body of knowledge and requires a high degree of skill. But preventive medicine must function in conjunction with diagnosis, treatment and rehabilitation. These are the four basic elements of every physician's continuous plan of medical care for each of his patients.—W. G. Smillie, M.D., Medicine as a Social Instrument: Preventive Medicine, *New England Journal of Medicine,* March 1, 1951.

COUNCIL ON PHARMACY AND CHEMISTRY

The following paper is published as a supplemental report to previous reports on organomercurial compounds submitted to the Council (J. A. M. A. **136:***36 [Jan. 3] 1948;* **137:***858 [July 3] 1948;* **140:***401 [May 28] 1949).*

The authors propose two tests as valid methods of evaluating the relative potency of antiseptics. These tests are performed on laboratory animals and are based on the protective power of antiseptics against lethal doses of tetanus spores. Antiseptics are evaluated by their ability to prevent death under the conditions of the tests.

In the first test, a lethal dose of tetanus spores, suspended in a necrotizing agent, is injected under the shaved skin of the animal. The antiseptic to be tested is then injected into the bleb formed by the suspension of spores. This method of evaluation would simulate conditions of use more closely and be more convincing if, after injection of the tetanus spores, the antiseptic were injected at varying times.

In the second test, the antiseptic is injected first and the suspension of tetanus spores is injected afterward into the same area at varying intervals of time. This test scarcely approximates the conditions of actual use.

USE OF TETANUS SPORES FOR TESTING ANTISEPTICS IN VIVO

John H. Brewer
and
C. Baxter McLaughlin, Baltimore

In a report of Jan. 3, 1948,[1] the Council on Pharmacy and Chemistry of the American Medical Association suggested that the "field of usefulness of organic mercurials should be explored, proved and defined. The proponents of these preparations should proceed seriously and diligently to this task." In following this suggestion of the Council we have developed a method which simulates conditions of use instead of employing test-tube experiments. We believe that this method encompasses the features required of a feasible antiseptic test, since the experiment takes place entirely in the animal body. Because death serves as the end point, it is unnecessary to read questionable clinical results or interpolate measurements.

Past studies have been criticized on the ground that streptococci and pneumococci change in virulence. Reported differences in antiseptic activity may be traced to insufficient mouse passage. Also, in the case of streptococci, pneumococci and anthrax, death in the experimental animal is due to a generalized septicemia. Consequently, an organism was sought which would not change in virulence and would cause death even if very small foci of infection developed. A strain of Clostridium tetani with which we had worked for many years was chosen; its virulence is constant and it can be relied upon to cause death in white mice even though the foci of infection are so small as to escape detection.

Spore suspensions of this organism were prepared and freed from vegetative cells by a previously described technique,[2] and the stock suspension was made to contain about 1,000,000 spores per milliliter.

[2] McLaughlin, C. B., and Brewer, J. H.: Toxin Production from Non-Toxin Producing Clostridium Tetani, read before the Society of American Bacteriologists, May 19, 1949, Cincinnati.

In order to approach actual conditions in which antiseptics are used and because we could not consistently infect through skin abrasions,[3] we resorted to other routes of infection.

We originally employed an intramuscular technique in which the tetanus spores and antiseptics were mixed in vitro and injected into the mouse.[4] By means of this technique, many of the common antiseptics were capable of preventing death in most of the animals. Since this was partially an in vitro test, Dr. Henry Welch, of the Food and Drug Administration, suggested that we inject the spores separately. In this type of test, however, results were inconsistent mainly because of our inability to relocate exactly the site of injection.

The classical experiments with tetanus indicate that it produces fatal infection primarily in deep puncture wounds,[5] and, therefore, a bleb containing tetanus organisms raised just under the surface of the skin might not be fatal in animals. However, it was decided to mix the spores with a necrotizing agent (6% $CaCl_2$ solution)[6] and to raise a bleb with 0.1 ml. injection just under the skin. All animals so treated died within four days with typical tetanus convulsions.

The experimental technique is to prepare a suspension of spores that contains between 10 and 100 m.l.d. per 0.1 ml. Dilution is made with 6% $CaCl_2$ solution. A bleb is raised under the shaved skin on the back of a mouse (20-25 gm.) by injection of 0.1 ml. of the prepared suspension. Into this bleb is injected 0.1 ml. of the antiseptic being tested. Extreme caution must be observed at this point to make sure that the antiseptic is injected into the original bleb. The success of the test is determined mainly by the care with which this is done.

This type of test was performed in order to determine the ability of commercial preparations of various antiseptics to prevent death under these conditions. The undiluted commercial preparations of antiseptics varied greatly in ability to prevent infection. This observation was confirmed by the close correlation of results in two separate laboratories, shown in the following table.

It was suggested that exposure of the tetanus spores to the direct action of the antiseptics might affect the toxin-producing mechanism of the organisms but not affect the growth of the bacteria. In this case, the treated animal would not die and death then could not serve as an end point. To eliminate this possibility, we exposed 1,000,000 spores of Clostridium tetani to 9 cc. of 2% aqueous merbromin for 24 hours. Tetanus-toxin-producing media containing sodium thioglycollate as a mercurial neutralizer was then inoculated with this tetanus-merbromin mixture. Growth from these treated spores was similar to that of organisms which had not been exposed to the mercurial. Animal titrations indicate that this treatment did not impair the toxin-producing ability of the organisms.

TABLE 1.—*Relative Efficacy of Certain Antiseptic Substances in Experimental Tetanus* *

‡ Bacteriological Research Laboratories, Hynson, Westcott & Dunning, Inc., Baltimore.

This technique of injecting tetanus spores and antiseptics separately into blebs in animals demonstrated that fatal infection could be prevented according to the efficacy of the antiseptic. The test was then redesigned to determine, if possible, the duration of antiseptic effectiveness. Specifically, does the antiseptic stay in the place where applied, or is it diffused, absorbed, or neutralized in some fashion by the animal body? For this investigation the following procedure was adopted:

The antiseptic to be tested was first introduced into the animal body by injection and later, at stated intervals, the usual mixture of test organisms (tetanus spores) and $CaCl_2$ solution was injected into the original bleb. The basic idea of antisepsis is that antiseptics should be effective over a period of time, not only to destroy or to prevent the growth of pathogenic organisms present in a wound, but also to prevent subsequent or secondary infection. Table 2 shows the lasting protection provided by certain antiseptics under conditions of this test.

TABLE 2.—*Lasting Protection Afforded by Various Antiseptics (Percentage Protected)* *

Thimerosal....................	6	20	20	0	0	0
Control........................	0	0	0	0	0	0

* A total of 920 mice were used in this experiment.

COMMENT

It is not suggested that any of these antiseptics can be depended on to prevent infection by tetanus organisms in deep puncture wounds. Also, the exact ratios of protection depend upon the number of lethal doses of spores injected, a technical feature which should be observed by anyone attempting to follow this technique. For example, if one uses too few viable spores, a higher percentage of protection is afforded by a given antiseptic; but death does not occur in all the controls. On the other hand, too many viable spores cause a low rate of protection but kill all the controls. In order to obtain consistent results, one should determine the minimum number of spores that will kill all of the controls and use some reasonable multiple of this for the test. Such a test may be duplicated in other laboratories. We routinely use approximately 10 M. L. D. as the challenge dose in our tests, even though an antiseptic is rarely called upon to protect against even one lethal dose of a pathogenic organism.

The percentage of protection afforded by the various antiseptics under the conditions of these experiments has been derived from experiments utilizing more than 2,600 mice. At least 10 mice were used in every test at each dilution and each time interval. Proficiency in finding the site of original injection is acquired only by practice in the technique. In these experiments, the results have been remarkably consistent, but only after a series of experiments to develop technique.

Iodine (2% aqueous), which has a good antiseptic rating with most investigators, shows up well when the organisms are injected immediately following the antiseptic. However, when an hour or more is allowed to elapse between antiseptic and tetanus spore injections it is not effective, indicating that it is quickly absorbed or neutralized.

Explanation of the mechanism of activity of the various antiseptics has not been attempted. However, one might reason that since the antiseptic activity of the various mercurial preparations varied so greatly, it may depend on the actual amount of antiseptic present in the marketed strength of the different solutions. Merbromin (mercurochrome®), which gave the best protection over an extended time period, is supplied in a 1:50 (2%) dilution. Nitromersol was used in a 1:500 dilution, and thimerosal is routinely used in a 1:1,000 dilution.

SUMMARY

A new technique, employing living animals, has been developed for testing antiseptics. It is submitted that these tests closely approximate conditions of actual use. Results of this study prove the efficacy against infection of certain commercial antiseptics when used in the animal body. The duration of protection against infection is determined by the property of some antiseptics, particularly certain mercurials, to remain active at the site of infection in the living animals for as long as 24 hours.

COUNCIL ON FOODS AND NUTRITION

The following statement was accepted by the Council and presented before the House Select Committee to Investigate the Use of Chemicals in Food Products, House of Representatives, Eighty-First Congress, Second Session, created pursuant to H. Res. 323. JAMES R. WILSON, M.D., *Secretary.*

CHEMICAL ADDITIVES IN FOODS

"A wholesome food is a product which makes a significant contribution to human dietary requirements and which is clean and free from micro-organisms and chemical additives of such quality or in such quantity that they may be directly injurious or result in reduced nutritional quality." This definition has been accepted by the Council on Foods and Nutrition. A portion of the statement accompanying this definition reads: "Although these basic concepts have acquired general recognition, the development recently of a large number of chemical technologic aids has emphasized the necessity for re-examining our idea of a wholesome food, particularly from the point of view of its freedom from chemical additives which may be harmful to the consumer because of toxicologic effects or because their incorporation in food causes or makes possible the reduction of nutritive value."

Chemical additives may appear in foodstuffs incidental to the production of the food or to its processing or packaging.

Chemical additives may be intentionally introduced into foodstuffs in order to improve the nutritive quality of the food (such as the addition of vitamin A to margarine) or to impart some particular quality, such as a desired texture or color, to the product. Some intentional additives may improve the keeping quality of food products.

It is apparent that chemical additives present in food may alter the nutritive quality of the foodstuff—either improve or dilute the nutritive quality. In addition, the presence of chemical additives in food poses the question of the hazard involved in their use due to their potential toxic qualities.

The possible toxicity of chemical additives to foods presents to us the difficult task of ascertaining the safety of an agent for daily or frequent ingestion throughout the life-span of men in both health and disease. In the case of the incidental chemical additives uncertainty of their presence or absence in food products presents the problem of accurate practical tests for their detection and quantitative determination.

Considerations of this sort lead to the acceptance by the Council at its annual meeting in 1949 of the following statement (*J. A. M. A.* **142**:259 [Jan. 28] 1950):

"The introduction of numerous new synthetic organic pesticides offers promise for increasing the nation's food supply and improving health through the control of insects and other pests. Past experience, however, indicates that poisons cannot be used safely on food crops without the development of certain fundamental knowledge concerning the poisons. What these materials will do to pests and food crops and to the workers who handle them must be known, and there must be developed, also, a knowledge of what these materials will do to warm-blooded animals and man when small amounts of residue are incorporated in their foods. Furthermore, practical methods of analysis should be available to permit identification and measurement of residue that may persist on or in consumer products. Such essential information is undeveloped for many of the agricultural poisons now in use.[1]

"It is the opinion of the Council on Foods and Nutrition that the information on the following factors should be supplied before pesticides, that may contaminate food or forage crops, are released for general use: (1) Chronic as well as acute toxicity tests. These should be carried out in such a manner as to demonstrate satisfactorily the toxicologic effects of pesticides on warm-blooded animals and man. (2) Accurate methods of isolation and quantitative determination of pesticide residues in biologic material. These methods must be sufficiently rapid as to be of practical use in the examination of perishable foods.

"Thorough pharmacologic investigation and practical quantitative methods are two of the most vital and pressing current needs in this field. The fundamental requirement for the orderly development of needed information must not be ignored. Unless this information is supplied, safe methods for handling and use cannot be developed. Furthermore, unless this information is supplied before new agricultural poisons are released for general distribution, accidents may occur which will offset the potential benefits of these new materials and cause delay in their adoption."

Intentional chemical additives may, as has already been noted, permit the lowering of the proportions of important food ingredients in the product and thereby result in a dilution or deterioration in nutritive value of the food. If the food happens to be a basic one, this effect may be cause for real concern.

The Council recognizes the important advantage of the proper use of such agricultural aids as pesticides and of certain of the intentional chemical additives. It holds, however, that proper information concerning the toxicologic effects, the possibilities of residues in foodstuffs, methods of detection and assay, must be developed before a pesticide which is likely to find its way into foodstuffs is permitted to be marketed.

Intentional chemical additives, especially those likely to find their way into basic foodstuffs or to find widespread application in a variety of foods, each of which may be infrequently eaten, must not be permitted until the complete harmlessness of these agents can be demonstrated beyond reasonable doubt. Furthermore, the use of additives which lead to a significant decrease in nutritive value should not be permitted.

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

The Beech-Nut Packing Company, Canajoharie, New York.

BEECH-NUT COOKED BARLEY CEREAL. Ingredients: Barley flour, casein and non-fat dry milk solids, dried malt syrup, dried Brewer's yeast, dicalcium phosphate, salt, sodium iron-pyrophosphate and thiamine hydrochloride.

Analysis (submitted by manufacturer).—Total solids 93.8%, moisture 6.2%, ash 5.4%, fat 3.3%, protein 15.2%, crude fiber 1.0%, carbohydrates other than crude fiber (by difference) 68.9%.

Vitamins and Minerals	Per Hundred Grams
Thiamine	1.66 mg.
Riboflavin	1.62 mg.
Niacin	5.3 mg.
Calcium	800 mg.
Phosphorus	1000 mg.
Iron	50 mg.
Copper	0.8 mg.

Calories.—3.7 per gram; 106 per ounce.

Use.—For use in the feeding of infants and young children

International Nutrition Laboratories, Inc., Mount Vernon, Ohio

SOYALAC—HYPO-ALLERGENIC INFANT FOOD. Ingredients: Soya bean solids, dextrose, maltose, dextrin, sucrose, soya oil, olive oil, salt, dibasic calcium phosphate, calcium carbonate and ferric ammonium citrate.

Analysis (submitted by manufacturer).—*Protein* (N × 6.25) 22.73%, fat 25.77%, fiber 0.68%, carbohydrate 44.08%, ash 3.86%, moisture 2.85%, calcium 0.73%, phosphorus 0.33%, iron 0.017%.

SOYALAC as liquefied in the following designated proportions yields the following percentages:

	1:7	1:6
Protein	2.88%	3.25%
Fat	3.22%	3.68%
Carbohydrate	5.51%	6.30%
Moisture	87.70%	86.07%
Calories per fl. oz.	20	22

Use.—For use as a hypoallergenic infant food.

---

[1] Since the acceptance of this statement, progress has been made and those manufacturers of pesticides who supported the work are to be congratulated.

SURGICAL TREATMENT OF LUMBAR DISK LESIONS

The literature of the past 15 years contains a number of contributions dealing with rupture of the intervertebral disk and propulsion of the nucleus pulposus into the spinal canal as a cause of intractable back pain and sciatica. The exact knowledge of the anatomy and embryology of this long-neglected structure dates back to the anatomic studies of von Luschka. A correct clinical or pathological approach to the subject, however, is a recent contribution. The accurate and painstaking necropsy studies of Schmorl provide scientific basis for the role assumed by this structure in a number of clinical conditions. The earliest clinical report of this condition was that of Goldthwaite, who reported a case of sciatica and paraplegia due to posterior herniation of the intervertebral disk at the lumbosacral junction. He suggested that such displacements might be the cause of many cases of sciatica, lumbago, and back strain. Mixter and Barr established the clinical relationship between the protruded nucleus pulposus and intractable back pain and sciatica in certain cases.

O'Connell,[1] in his Hunterian Lecture (Feb. 16, 1950), analyzed the results of surgical treatment of 500 cases of proved lumbar intervertebral disk protrusion on which he operated between January, 1938, and May, 1948, at St. Bartholomew's Hospital. O'Connell infers from his experience that back pain from a disk protrusion is seldom so severe, so persistent, or so frequent as to require operation. Occasionally, pain affected both lower limbs, either simultaneously or in succeeding attacks. In over 90% it was felt in one leg alone, and the left was involved more often than the right in the proportion of three to one. A clinical diagnosis of lumbar intervertebral disk protrusion is more accurate than a myelographic diagnosis. O'Connell believes that it is unnecessary to perform either lumbar puncture or myelography to make a diagnosis. The diagnosis is readily made in most patients by careful clinical and radiologic study. The problem is not in diagnosis but in the decision as to the correct treatment.

The early enthusiasm and the operative furor that followed the discovery of the role of the protruded disk in the causation of back pain and sciatica were soon followed by a more critical attitude in view of the many disappointing results. O'Connell justly remarks that the natural history of lumbago and sciatica has not been altered by the discovery of their common cause and that the tendency to spontaneous recovery remains as strong as it has been through the centuries. Rest during the stage of acute symptoms, with later exercises for the lumbar muscles and joints, constitutes the correct treatment in most patients. Only when an adequate trial of such measures fails to bring relief should surgery be considered. O'Connell's series of 500 patients treated surgically represents but a small proportion of patients seen in the outpatient department in whom a clinical diagnosis of protruded lumbar intervertebral disk has been made. He concludes that excision of a lumbar intervertebral disk protrusion is required in only a small proportion of patients with this lesion. A careful clinical and radiologic examination of cases of lumbago and pain in the lower limb provides good evidence not only of the presence of a lumbar intervertebral disk protrusion but also of its anatomic level, size and relationships. In most of the selected cases, a carefully performed operation designed to relieve the affected nerve fibers from forces that stretch and compress them will give satisfying relief of symptoms. In his series, 92% of the patients were either completely free from symptoms or very greatly improved after operation.

In his discussion of the causes of unsatisfactory results from the operative treatment of lumbar disk lesions, Armstrong[2] stresses that there were in the reported series between 5% and 40% of unsatisfactory results. A wrong diagnosis is perhaps the most frequent cause of unsatisfactory results from operation. The causes of failure, according to this author, in patients with genuine disk lesions who are not relieved by operation are failure to locate the lesion, or failure to recognize a double lesion. In 12% to 20% of all patients, both the disk between the 4th and 5th lumbar vertebrae and the disk between the 5th lumbar and 1st sacral vertebrae are affected simultaneously; such a double lesion cannot be recognized clinically. Other causes are failure to deal with a bilateral lesion and subsequent further retropulsion of nuclear tissue. It is not enough to remove the displaced nuclear tissue alone; the whole diseased nucleus must be removed. The root may be damaged while it is being freed or by too vigorous retraction. In a definite number of cases, subsequent prolapse of a previously healthy disk can take place. There may be permanent changes in the nerve root, damage to the posterior articular facets, and arthritis of the intervertebral joint.

---

[1] O'Connell, J. E. A.: Protrusion of the Lumbar Intervertebral Discs: A Clinical Review Based on 500 Cases Treated by Excision of the Protrusion, J. Bone & Joint Surg. 33-B: 8 (Feb.) 1951.

[2] Armstrong, J. R.: The Causes of Unsatisfactory Results from the Operative Treatment of Lumbar Disc Lesions, J. Bone & Joint Surg. 33-B: 31 (Feb.) 1951.

Armstrong is opposed to the performance of arthrodesis in addition to the removal of the herniated material. He feels that it is unnecessary for the vast majority of patients and that it increases the immediate operative difficulties and hazards and greatly increases the period of postoperative incapacity. When necessary, arthrodesis can be performed in a second stage. Postoperative infection in the form of wound infection, meningitis, or osteomyelitis of the vertebral bodies can occur. Such complications as gross damage to the spinal theca, to the cauda equina, or to extrathecal nerve roots can be largely avoided by proper surgical technique.

The views expressed by the British surgeons are very much in agreement with those of the surgeons this side of the Atlantic.

FOLIC ACID

Folic acid is the official name for a pteroyl acid ester containing paraaminobenzoic acid and one molecule of glutamic acid. This compound is also known as pteroylglutamic acid or folacin. It is considered to be a member of the vitamin B complex and was first prepared synthetically in 1946.[1] It has been shown to serve as an essential metabolite for a number of bacteria, including Lactobacillus casei and Streptococcus lactis R, and for growth and red cell development in the chick. It will cure certain nutritional macrocytic anemias in man and is active hematologically in pernicious anemia, although it does not prevent the development of neurological complications.

Folic acid occurs widely in nature, both free and in the form of conjugates containing either two or six additional glutamic acid groups. These can be converted to pteroylglutamic acid by the action of specific enzymes.[2] Recently, evidence has accumulated that indicates that the biologic activity of folic acid is actually vested in one or more of its metabolic products. In 1948, Sauberlich and Baumann [3] reported that crude liver extracts, yeast extracts, bacto®-peptone and a rice-bran concentrate contain a substance essential for the growth of Leuconostoc citrovorum and that the concentration of this so-called citrovorum factor does not parallel that of either folic acid or of the antipernicious anemia factor. Folic acid in high amounts did support the growth of the bacteria, but only after a delay of 24 to 36 hours. It was further shown that, when rats or humans are fed large amounts of folic acid, increased amounts of citrovorum factor appear in the urine.[4] Nichol and Welch [5] have reported that liver of folic-acid-deficient rats is low in both citrovorum factor and folic acid and that addition of folic acid to slices of such liver and to normal livers increases the amount of citrovorum factor, the yield being further increased by the addition of certain reducing agents, particularly ascorbic acid. They also showed that the conversion of folic acid to citrovorum factor is inhibited by the folic acid antagonist 4-aminopteroylglutamic acid (aminopterin) and that the citrovorum factor is much more effective than folic acid in protecting rats against the toxic effects of 4-aminopteroylglutamic acid.

In independent studies on the metabolism of folic acid, Shive and his co-workers [6] isolated from enzymatic digests of hog liver a crystalline substance which was considerably more active than folic acid in protecting a number of bacteria against the toxic action of methylfolic acid and which supported the growth of L. citrovorum. They called this substance folinic acid and showed it to be present in high amounts in crude liver extracts, hog duodenal mucosa and grass and in much lesser amounts in milk, muscle tissue and yeast extract. Paper chromatography studies of hog liver extracts indicated the presence of a group of compounds, the folinic acid group, all of which possess activity similar to that of folinic acid. Mild acid hydrolysis destroys the folinic acid activity, but the compound formed has biologic activities corresponding to folic acid. Recently, these investigators,[7] and Brockman [8] and his associates described the synthesis of preparations with the properties of folinic acid.

Preliminary experiments indicate that folinic acid preparations promote blood regeneration in persons with pernicious anemia, nutritional macrocytic anemia and tropical sprue in relapse,[9] reverse the toxic effects of folic acid antagonists in man [10] and replace folic acid in the diet of the chick.[11]

Since at least one organism requires preformed folinic acid, since all organisms can apparently use folinic acid in place of folic acid and since folinic acid is more effective than folic acid in overcoming the inhibitory effects of folic acid antagonists, it is probable that folinic acid is the enzymatically active form of the vitamin or represents it more closely than folic acid. As has recently been pointed out,[12] an analogous situation obtains in the vitamin B_6 group. In this case, pyridoxine was the first form of the vitamin discovered. Later pyridoxal and pyridoxamine, both more active than pyridoxine, were found to constitute most of the vitamin B_6 activity in natural diets; it is now believed that pyridoxal phosphate is the form of the vitamin actually used for metabolic purposes.

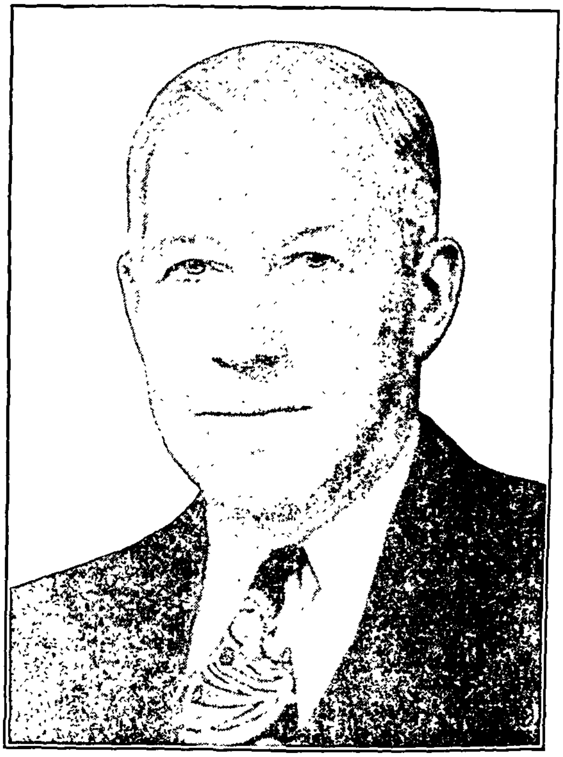
THE PRESIDENT-ELECT—DR. LOUIS H. BAUER

In recognition of his long and distinguished service to medicine, the House of Delegates of the American Medical Association at the 100th annual session in Atlantic City, June 14, elected Dr. Louis H. Bauer of Hempstead, N. Y., to the position of President-Elect. Dr. Bauer has been a member of the Board of Trustees of the American Medical Association since 1944 and Chairman of the Board since 1949; he became a member of the Executive Committee in 1947 and was Chairman of the Committee in 1948. He was for many years a member of the House of Delegates, served as Chairman of the Council on Medical Service and as a member of the Committee on Scientific Exhibit. Previously, he had been president of the Nassau County Medical Society and of his district branch medical society, speaker of the House of Delegates of the Medical Society of the State of New York and president of his state medical society. Dr. Bauer was born in Boston and graduated cum laude from Harvard Medical School. He interned at Mercy Hospital in Springfield, Mass., was an honor graduate from the United States Army Medical School and of the United States Army School of Aviation Medicine, and a graduate also from the Army War College in 1926. Dr. Bauer spent 13 years in the Army as a medical officer and was the first Commandant of the Army School of Aviation Medicine. He is now a colonel, United States Army, retired. He was also the first medical director (from 1926 to 1930) of the Aeronautics Branch of the United States Department of Commerce, now the Civil Aeronautics Administration. Since 1930, Dr. Bauer has been in private practice in cardiology at Hempstead. He is attending cardiologist at Nassau Hospital, Mineola, and a consultant at Meadowbrook Hospital in his home town and at some six other hospitals in near-by communities. He is a diplomate of the American Board of Internal Medicine, a fellow of the American College of Physicians, a member of the American Heart Association, of the New York State Public Health Council, and of the Aero Medical Association, of which he was the first president (from 1929 to 1931), an honorary member of Phi Beta Kappa, and was a delegate from the American Medical Association to the American Council on Rheumatic Fever. He received the Distinguished Service Award of the Nassau *Daily Review-Star* in 1949, and was the first recipient of the Lister Award of the Aero Medical Association and of the John Jeffries Award of the Institute of Aeronautical Sciences. For 21 years, he has been editor in chief of the *Journal of Aviation Medicine*. He has contributed many articles on aviation medicine, cardiology, and medical economics to medical journals, is the author of a textbook on aviation medicine, of a book entitled "Private Enterprise or Government in Medicine," and of chapters on aviation medicine in various textbooks and encyclopedias. Dr. Bauer was secretary of the American committee of the World Medical Association and a member of the council of this organization and since 1948 has been Secretary General of the World Medical Association. His election to the position of President-Elect of the American Medical Association is an honor richly deserved for outstanding and faithful service to the profession, to the public, and to his country.



Louis H. Bauer, M.D.
President-Elect of the American Medical Association

LIVER IN EXPERIMENTAL HYPERTENSION

Accumulating evidence indicates that the liver plays an important role in the regulation of systemic blood pressure. Recent experiments[1] have shown that reduction of the blood flow to the liver decreases the blood pressure of dogs with experimental hypertension. In these studies, partial occlusion of the portal vein by means of a Goldblatt clamp was followed by a gradual return of the elevated blood pressure to normal levels. This effect presisted throughout the period of observation, which in some animals extended for more than a year. It was not abolished by the subsequent establishment of a portacaval shunt, indicating that the alterations in the systemic pressure were not due merely to the accumulations of blood in the splanchnic area. Complete interruption of the arterial blood supply to the liver also reduced the blood pressure of the animals to normal, but in this case the hypotensive effect persisted for only a few weeks, presumably because of a compensatory increase in the blood flow through the portal vein. The most consistent reduction of blood pressure was obtained when both the hepatic artery and the portal vein were partially occluded.

During the experiments it became apparent that the decrease in blood pressure was dependent on the production of a mild chronic liver insufficiency. Unless the reduction in blood flow was sufficient to produce fatty infiltration of the liver cells, no hypotensive effect was noted. Usually such histologic changes were accompanied by laboratory evidence of diminished liver function, but the disturbance was surprisingly slight. The foregoing observations confirm the earlier work of Page, McSwain, Knapp, and Andrews,[2] who were able to reduce blood pressure in experimental hypertension by poisoning the liver with a mixture of carbon tetrachloride and alcohol.

Two possible explanations for the reduction of blood pressure under these circumstances have been advanced. One is that the damaged liver is unable to manufacture hypertensinogen, an essential participant in the pressor reaction of renal hypertension, and that this effectively blocks the reaction. A second possibility is that the anoxemic liver produces an active vasodepressor material such as that demonstrated by Shorr and co-workers [3] in liver slices under anaerobic conditions and in the blood of animals in shock. This vasodepressor substance then presumably neutralizes the vasoexcitor substance elaborated by the anoxemic kidney. Perhaps both of these mechanisms are active. More work will be required before these questions can be answered with certainty or before any conclusions can be drawn as to the significance of these factors in man, but the facts already established are of great theoretical importance.

ALLEN WHIPPLE AWARDED DISTINGUISHED SERVICE MEDAL

Allen O. Whipple, M.D.
Awarded Distinguished Service Medal

At the annual meeting in Atlantic City, June 11, the House of Delegates of the American Medical Association awarded the Distinguished Service Medal of the Association to Dr. Allen O. Whipple of New York, an outstanding surgeon and medical investigator. Dr. Whipple was born in Persia, where his parents were missionaries. He graduated from Princeton University in 1904, received his medical degree from the College of Physicians and Surgeons of Columbia University in 1908, and has practiced medicine in New York City since 1910. He was appointed instructor in surgery in 1911 and was professor of surgery at the College of Physicians and Surgeons and director of the surgical service at Presbyterian Hospital in New York for many years. After his retirement from those positions, in 1946, he accepted a position on the faculty of the American University of Bierut, where, as a trustee of the University, he helped plan the new teaching hospital, one of the pioneer medical centers in the Near East. In 1946, Dr. Whipple was appointed clinical director of the Memorial Hospital in New York. His distinguished career has brought many honors, including the Judd Award of the Memorial Hospital in 1946, for having made "the greatest advancement toward the discovery of a cure for cancer," and the Bigelow Medal of the Boston Surgical Society, for contributions to the advancement of surgery. He is a past president of the American Surgical Association and one of the founders group of the American Board of Surgery. He was a member of the Commission on Graduate Medical Education, created in 1938 to help formulate the principles involved in graduate medical training. The esteem in which he was held by his colleagues required his appearance before many scientific societies. Among his notable addresses were the Lister Oration before the annual meeting of the Canadian Medical Association, the Arthur Dean Bevin Lecture of the Chicago Surgical Society, the Stewart Memorial Lecture of the Pittsburgh Academy of Medicine, and the annual Hodgen Lecture before the St. Louis Surgical Society. He is a member of the Surgical Research Society, the New York Surgical Society, the Society of Clinical Surgery, the Practitioners Society, the Society of University Surgeons, the American College of Surgeons, the Medical Society of the State of New York, the American Medical Association, the New York Academy of Medicine, the Century Club, and the Sheraka Club. He maintains an interest in oriental languages and in landscape painting, although still director of surgery at the Memorial Hospital, one of the outstanding centers of the world for cancer research and the treatment of patients suffering from cancer. During World War II, Dr. Whipple was chairman of the Subcommittee on Infected Wounds and Burns of the National Research Council. He has been a prolific writer, contributing especially to surgery of abdominal cancer, and is on the editorial advisory board of the *Annals of Surgery*.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

Investigation—Hoxsey Cancer Clinic

Senator Langer of North Dakota introduced Senate Resolution 142, authorizing the Senate Committee on Labor and Public Welfare to conduct a study of the Hoxsey Cancer Clinic of Dallas, Texas. The committee would be authorized to make a complete study and investigation to ascertain whether the methods employed by the Hoxsey Cancer Clinic in the treatment of cancer have proved to be a cure for such disease. The committee would be further directed to make a report to the Senate at the earliest practicable date, showing the results of its study and any recommendations.

School Health Services

H. R. 4322, introduced by Representative Mitchell of Washington, would provide for the general welfare by enabling the several states to make more adequate provision for the health of school children through the development of school health services for the prevention, diagnosis and treatment of physical and mental defects and conditions. This bill is identical with three other House bills and with S. 1411 of the last Congress, which passed the Senate but failed passage in the House.

Problems of the Aging

Representative Yates of Illinois introduced House Resolution 238, which would authorize a select committee on problems of the aging to be composed of seven members of the House of Representatives, all appointed by the Speaker. The committee would be charged with investigating the status of the older age group with respect to its manpower potential and, further, with determining the basic problems of this group in the fields of employment, health, education, and community services, and the federal government's responsibilities to the group. The committee would be instructed to report to the House as soon as practicable, during the present Congress, the result of its study, together with recommendations.

STATE LEGISLATION

California

Bills Introduced.—S. 1457, proposes the creation of a state board of chiropractic examiners and proposes, among other things, that **minor surgery or ambulant surgery** are those branches of surgery which consist of operative procedure by electrical or other methods which do not include the opening of the thoracic, abdominal, or cranial cavities or the amputation of limbs. S. 1818, proposes to **exempt from the sales tax** drugs dispensed on prescriptions filled by registered pharmacists for persons licensed and authorized to prescribe drugs under the business and professions code.

Bill Enacted.—A. 2672 has become Chapter 788 of the Laws of 1951. It amends the Business and Professions Code by providing that whenever the words **"diagnose" or "diagnosis"** are used, they shall include any undertaking by any method, device or procedure whatsoever, and whether gratuitous or not, to ascertain or establish whether or not a person is suffering from any physical, mental or nervous disorder. The terms shall specifically include the taking of a person's blood pressure and the use of mechanical devices or machines for the purpose of representing to any person any conclusion with respect to such person's physical, mental or nervous condition.

Connecticut

Bills Introduced.—H. 326, proposes to authorize **medical group clinics** to form corporations without capital stock for the purpose of operating and maintaining a medical clinic. H. 1705, would permit a **non-profit medical service corporation** to make payment for the professional services of dentists. S. 690, proposes the appointment of a commission to investigate and make recommendations relating to drafts of proposed legislation for expanding the opportunities for **medical education** in Connecticut for qualified residents.

Bill Enacted.—H. 546 has become Public Act. No. 104 of the Acts of 1951. It directs the State Department of Health to maintain **laboratories** and bureaus of administration, vital statistics, preventable diseases, sanitary engineering, maternal and child hygiene, public health nursing, public health instruction, venereal diseases, mental hygiene, and industrial hygiene.

Florida

Bills Enacted.—H. 302, was approved May 30, 1951. It provides regulations for the licensing of registered and practical **nurses**. H. 579, was approved May 29, 1951. It amends the law relating to the practice of medicine by requiring licentiates to **annually register** their licenses with the state board of health. H. 1084 became law without approval May 29, 1951. It authorizes the Board of County Commissioners of Orange County to provide for life, health, accident, **hospitalization**, and annuity insurance for its employees and their families. S. 71 became law without approval May 29, 1951. It directs the State of Florida to pay to the **first accredited and approved medical school** established within the state the sum of Three Thousand Dollars ($3,000) per year for each student admitted and enrolled in such institution. S. 326 became law without approval May 31, 1951. It provides that whenever the **dead body of a human being** shall remain unclaimed by any relative of the deceased person for a period of ten days after death, the board of county commissioners of the county within which such body may be shall have authority and power to give such body for any educational or research purpose to any medical school, dental school, school of nursing or other college or university, whether within or without the State of Florida. S. 817 was approved May 23, 1951. It establishes a Madison County Health and Hospital Board in Madison County to institute, maintain and operate a **public health program** for the citizens of the county and to own and operate a hospital therein. S. 841 became law without approval May 28, 1951. It authorizes the Board of Commissioners of Polk County to provide **group insurance** for its employees.

Illinois

Bill Introduced.—H. 1074, to amend the Civil Administrative Code, proposes the creation of five man committee composed of reputable chiropractors licensed to practice **chiropractic** in the state for the purpose of examining applicants for a chiropractic license to treat human ailments without the use of drugs or medicine and without operative surgery. H. 1161, proposes new regulations for the organization of **non-profit hospital service corporations**. S. 600, proposes to authorize the Department of Registration and Education to examine for and grant licenses to practice **physical therapy** which is defined as the treatment of any body or mental condition of any person by the use of the physical, chemical, and other properties of air, heat, light, water, electricity, massage, and active and passive exercise. The use of roentgen rays and radium for diagnostic and therapeutic purposes, and the use of electricity for surgical purposes, including cauterization, would not be authorized under the term "physical therapy." S. 613, proposes the enactment of a system of **temporary disability benefits**. S. 638, proposes to authorize the use of the **injunction** to enforce the provisions of the Chiropody Practice Act. S. 641, proposes to permit the use of the **injunction** to enforce the provisions of the Pharmacy Practice Act. S. 642, proposes to permit the use of the **injunction** to enforce the provisions of the Public Health Nursing Act. S. 647, proposes to permit the use of the **injunction** to enforce the provisions of the Medical Practice Act.

Bill Enacted.—S. J. R. 25 was adopted May 16, 1951. It requests an amendment of the **rules of the College of Medicine** of the University of Illinois in order to provide for the annual admittance of at least twenty students who will agree to practice in the rural areas of the state.

Massachusetts

Bill Introduced.—S. 665, proposes the creation of a commission to make an extensive investigation of all phases of the **employment security law**.

Nebraska

Bill Enacted.—Legislative Bill 530, was approved May 5, 1951. It relates to the commitment of persons to state institutions by providing that the petition accompanying the commitment must be accompanied by a certificate of a **legally qualified physician** with experience in the actual practice of his profession, certifying that he has personally examined the person to whom the application relates and that in his opinion the person is a feeble-minded person and a proper subject for commitment to the institution.

New Hampshire

Bills Enacted.—H. 263 has become Chapter 125 of the Laws of 1951. It makes it unlawful for an employer to require any employee or applicant for employment to pay the **cost of a medical examination** or the cost of furnishing any records required by the employer as a condition of employment. H. 404 has become Chapter 127 of the Laws of 1951. It amends the law relating to the practice of **nursing** by reducing the age requirement from 21 to 20 years.

Ohio

Bill Enacted.—S. 73 was approved May 11, 1951. It relates to the isolation and quarantine of persons exposed to and suffering from **communicable diseases**.

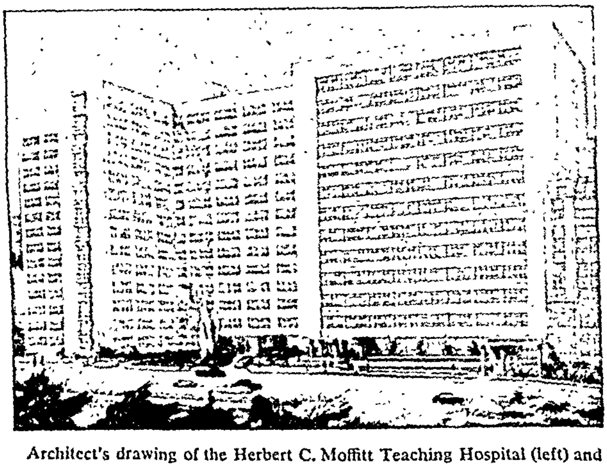
The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

MEDICAL NEWS

CALIFORNIA

Award in Psychiatry.—At the 1951 meeting of the American Psychiatric Association Dr. Jurgen Ruesch, associate professor of psychiatry at the University of California School of Medicine, and his associates at the Langley Porter Clinic, Robert E. Harris, Ph.D., Carole Christiansen, M.A., Martin B. Loeb, B.A., Sally Dewees, M.S., and Dr. Annemarie Jacobson, were honored by receiving the Hofheimer Award for research in psychiatry. The prize was awarded for a sociopsychological study of duodenal ulcer. The results of the inquiry were published in book form by the University of California Press in 1948.

University Medical Center.—The nucleus of a medical center, which will help bring California's medical education and research facilities more in line with the state's population growth, is under construction by the University of California at San Francisco. The new units of the medical center will cost about $22,630,000. The state legislature has appropriated $20,730,000 for the present program. Integrated in the state-financed structures will be quarters for the university's Cancer Research Institute, financed by a one million dollar contribution from the U. S. Public Health Service, and an area for research in ophthalmology, financed by a gift of $65,000 from Mr. and Mrs. Berthold Guggenhime of San Francisco. In addition, the U. S. Atomic Energy Commission is financing a $535,000 radiological laboratory. The two major units under construction are the 500-bed Herbert C. Moffitt Teaching Hospital and the Medical Sciences Building. These 14-floor units, accounting for $20,445,000 of the total cost, actually are planned as a single coordinated structure. Work is in progress on the teaching hospital and on two sections of the Medical Sciences Building. Completion of the hospital and the larger section of the sciences building is scheduled for the spring of 1953, when it will be possible to raze the dental-pharmacy building, which dates back to before the turn of the century, and undertake completion of the Medical Sciences Building. Remodeling of two buildings adjacent to the Medical Center for use in research on arthritis and corticotrophin (ACTH) will be done at a cost of $100,000. The radiological laboratory will be completed in a few weeks. For the first time since the earthquake and fire of 1906, the school of medicine will be unified. The new facilities will bring under one roof the school of medicine, the college of dentistry, the college of pharmacy, and the school of nursing.



Architect's drawing of the Herbert C. Moffitt Teaching Hospital (left) and the Medical Sciences Building (right), a single coordinate structure of the University of California Medical Center.

COLORADO

University Appointment.—Wilhelm Richard Frisell, instructor in physiological chemistry at Johns Hopkins University School of Medicine, Baltimore, has been appointed assistant professor of biochemistry at the University of Colorado School of Medicine, effective July 1.

Alumni Honor Veterans of Faculty.—Nine faculty members of the University of Colorado School of Medicine, Denver, were presented special medallions in recognition of 25 years of service at the annual alumni banquet June 2. The service recognition, established by the alumni last year, went to two members of the regular faculty and seven members of the clinical faculty: Dr. William C. Black, associate professor of pathology, and Dr. William B. Draper, professor of physiology and pharmacology, both members of the regular faculty; Dr. Wilford W. Barber, assistant clinical professor of pediatrics, Dr. Hamilton I. Barnard and Dr. J. Frederic Prinzing, both associate clinical professors of surgery, Dr. Harry J. Corper and Dr. Harry Gauss, both associate clinical professors of medicine, Dr. Lyman W. Mason, clinical professor of obstetrics and gynecology, and Dr. John I. Zarit, assistant clinical professor of medicine.

ILLINOIS

Hospitals to Care for Poliomyelitis Patients.—Facilities of 128 Illinois hospitals have been pledged for diagnosis or treatment of poliomyelitis patients this summer, Dr. Roland R. Cross, state director of public health, announced June 8. This is a culmination of years of effort on the part of public health agencies to enlist the participation of administrators of general hospitals in admitting poliomyelitis patients, he said. The committee has conducted a series of district meetings to inform hospital personnel in methods of caring for poliomyelitis patients. Of the 128 hospitals pledging help, 66 will provide diagnostic facilities only; 34 will provide diagnosis and treatment; 12 will give diagnosis, treatment, and rehabilitation care, and 16 will provide convalescent and rehabilitation care. Names of the hospitals are available through the Illinois State Department of Health, Springfield.

Chicago

Grants for Research.—The University of Illinois College of Medicine has been awarded the following grants in support of research investigations: $7,000 (renewal) by the Lakeland Foundation for the study of a cancer diagnostic test; $1,000 from Abbott Laboratories for an investigation concerning the effect of amines on high blood pressure in experimental cases, and $1,000 from the E. & J. Manufacturing Company of Glendale, Calif., in support of research studies on resuscitation. This investigative study on resuscitation is also supported by the American Red Cross and the American Medical Association.

Two New University of Chicago Hospitals.—Two new hospitals are to be added to the University of Chicago's Medical Research Center at a cost of over 4½ million dollars. The Charles Gilman Smith Hospital for research in and treatment of contagious and heart diseases will have six floors and 75 beds. The second hospital, to be the west wing of the clinics group, will be for research in orthopedics and in chronic diseases. This seven-story west wing will have 92 beds on three floors, including a special 20-bed unit for tuberculosis patients. The Charles Gilman Smith Hospital is named for a distinguished early Chicago physician, whose widow in 1926 left $285,000 to the university for a contagious diseases hospital. The fund has grown to $574,000. The U. S. Public Health Service made a grant of $485,000 through the National Heart Institute, which will provide for three floors for cardiac research. Hill-Burton funds are also being used to construct the hospitals. The 167 beds of the two buildings will bring the university's clinical facilities to 709 beds.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

MASSACHUSETTS

Harvard Alumni Day.—Some 500 doctors gathered in Boston May 25 for Harvard Medical School Alumni Day. The all-day meeting featured medical papers by members of the Harvard faculty and reunion dinners for various classes. The day began with morning visits to operations and hospital rounds at some of the teaching hospitals associated with the school. A medical symposium included talks by Drs. James H. Means, Herrman L. Blumgart, George W. Thorn, Derek E. Denny-Brown, George B. Wislocki, and Samuel A. Levine. A surgical symposium included talks by Drs. Edward D. Churchill, Merrill C. Sosman, Francis D. Moore, Grantley W. Taylor, Sidney Farber, and John Homans.

Industrial Hygiene Laboratory.—The occupational medical service at the Massachusetts Institute of Technology opened its new industrial hygiene laboratory in the Homberg Infirmary May 8. The new facilities will make possible extensive testing services for all departments and laboratories to assist in developing the most beneficial environment possible for all kinds of scientific and professional work. The problem of analysis and correction of hazards due to radioactive or toxic chemicals or dusts, as well as the more subtle problems of unusual occupational stress, noise, and lighting, are included in the assignment. The occupational medical service will act principally in an advisory capacity. All illnesses of institute personnel will be screened by the members of the occupational medical service and those that appear to be job-related will be carefully investigated. The service will work closely with the institute's safety committee, of which Prof. Edward R. Schwarz is chairman. In addition to special departmental seminars, a course in occupational hygiene is planned in the M. I. T. graduate school. The course is designed to provide background for research administrators and industrial hygiene consultants. Dr. Harriet L. Hardy, assistant medical director, will be in charge of the service.

MICHIGAN

Personals.—Dr. Osborne A. Brines, professor of pathology at Wayne University College of Medicine, Detroit, has been elected vice president of the International Society of Clinical Pathology. Dr. Brines will attend the International Congress of Clinical Pathology in London, England, July 17-20 as official delegate of the American Society of Clinical Pathologists.

McGregor Fund Grants.—Two grants totaling $96,378 have been awarded Wayne University College of Medicine, Detroit, by the McGregor Fund. The first grant will cover the salary of a full-time professor and chairman of the department of psychiatry in Wayne's college of medicine for a five-year period ending June 30, 1956. The professor's original appointment was made possible by a similar grant in 1946. The second grant provides $6,378 for two residency fellowship awards for the fiscal year commencing in July.

MISSOURI

New Hospital Psychiatric Unit.—Menorah Hospital, Kansas City, has announced the opening of its new psychiatric unit that has accommodations for the care of 32 patients. The physical facilities will make possible all modern methods of psychiatric treatment, including physical therapy, occupational therapy, and electric and insulin shock therapy, as part of an integrated approach to treatment. The staff includes a psychologist, psychiatric social worker, and an occupational therapist. Dr. Morton Jacobs is director of the psychiatric unit and chairman of the department of psychiatry.

MONTANA

Cancer Lecture Series.—The cancer committee of the Montana Medical Association, in cooperation with the state board of health, has presented a series of lectures on cancer throughout the state. They were held, beginning June 4, at Miles City, Billings, Great Falls, Kalispell, Butte, and Bozeman. The speakers at each of these lectures were Dr. Randolph H. Hoge, professor of gynecology, and Dr. Arthur B. Gathright Jr., assistant professor of medicine and assistant director, onocology department, Medical College of Virginia, Richmond.

NEW YORK

New Society of Radiologists.—Last fall the Northeastern New York Radiological Society was established in Albany with 34 charter members. Meetings are held four times a year, usually in Albany, but one meeting a year (in June) is to be held in another part of the state. The officers for the current year are Dr. Edward DeFeo, Brooklyn, president; Dr. Orville L. Henderson, Troy, vice president, and Dr. John F. Roach, Londonville, secretary-treasurer.

Westchester County Society Awarded Citation.—The 1951 Cancer Crusade Citation has been awarded to the cancer committee of the Medical Society of the County of Westchester by the American Cancer Society. The committee was cited for its broad school program employing a special cancer instruction text, "Youth Looks at Cancer," which was placed in the county high schools in 1940. The book has since been distributed nationally by the national society.

Department Head Appointed.—Dr. Clair E. Folsome, Plainfield, N. J., has been appointed head of the department of obstetrics and gynaecology at the New York Medical College, Flower and Fifth Avenue Hospitals. Dr. Folsome was formerly executive director of the National Committee on Maternal Health and executive director of research for the Ortho Research Foundation from 1944 to 1951. He will attend the French Congress of Gynecology in Paris as representative of the New York Medical College, Flower and Fifth Avenue Hospitals.

Personals.—Dr. Connie Myers Guion, chief of the medical clinic of New York Hospital-Cornell University Medical Center and consulting physician on the staff, received the award of merit of the Alumni Association of Cornell University Medical College April 21.——Dr. Sidney V. Haas, who recently completed his 50th year of service in the medical profession, was honored at a reception and buffet supper in Atlantic City, N. J., June 12 by the pediatric staff of the New York Polyclinic Medical School and Hospital. The occasion noted the publication of Dr. Haas' monograph, "The Management of Celiac Disease."——Dr. Julius Lempert, head of the Lempert Institute of Otology, New York, has returned from Stockholm, Sweden, where on May 30 he received the honorary degree of doctor of medicine from the Karolinska Institute in appreciation of his contribution to the treatment of deafness in otosclerosis.——As chairman of international relations of the American Society of Clinical Pathologists, Dr. Theodore J. Curphey will attend the International Congress of Clinical Pathology in London July 16 to 20. He has been invited to lecture at the monthly meeting of the Medico-Legal Society of Great Britain in London July 25. Dr. Curphey, chief medical examiner for Nassau County, will speak on "A Comparison of the Coroner and the Medical Examiner Systems in the United States."——Dr. Isador S. Ravdin, John Rea Barton professor of surgery at the University of Pennsylvania School of Medicine, Philadelphia, received an honorary degree of doctor of humane letters from the New York Medical College at graduation exercises June 6. He addressed the graduating class of the college, advocating the return to the old "family doctor" relations.

New York City

Dr. Lovejoy Receives Blackwell Medal.—Dr. Esther Pohl Lovejoy, New York, is the recipient of the 1951 Elizabeth Blackwell medal given annually by the American Medical Women's Association for "outstanding contribution to the advancement of women in medicine." The award was presented at the 36th annual meeting of the association in Atlantic City, June 8-10. Dr. Lovejoy became head of the board of health of Portland, Ore., in 1907. In 1917 she went to France to serve with the American Red Cross, returning to this country in 1919 to become the executive chairman of the American Women's Hospitals, a post which she has continued to fill. Dr. Lovejoy served as president of the Medical Women's International Association from 1919 to 1924 and as president of the American Medical Women's Association from 1932 to 1933. In recognition of her splendid work in foreign countries Dr. Lovejoy has been given the Gold Cross of the Legion of Honor (France); the Gold Cross of the Redeemer; the Gold Cross of King George I and the War

Cross, (Greece); the Gold Cross of the Holy Sepulcher (Jerusalem), and the Gold Cross of Saint Sava (Yugoslavia). She now is working on a revision of her book, "Certain Samaritans," a history of women in medicine.

Library Services.—The New York Academy of Medicine Library, one of the largest American medical collections, has on its shelves most of the important literature of medicine and much of the allied sciences in some 272,000 volumes. These resources are available to the general public as well as to the academy's own fellows and holders of library cards. Besides complete runs of the standard medical journals in English and foreign languages, and in addition to the usual medical textbooks and monographs, the library is particularly strong in foreign monographs, textbooks, encyclopedias, and systems; medical biography; medical history; medical Americana, and portraits of physicians. It has good files of health reports, government publications, medical school announcements, hospital reports, data on morbidity, and vital statistics. In fields related to medicine it has excellent collections on dentistry, chemistry, psychology and psychoanalysis, foods and cookery, as well as representative material in nursing, sociology, anthropology, physics, mathematics, botany, zoology, philosophy, pharmacy, and veterinary medicine. Out-of-town nonprofit libraries may also use its facilities. Books may be taken for two weeks and renewed for two additional two-week periods. Out-of-town fellows and subscribers may have material sent to them under the "interlibrary loan code," transportation to be paid by the borrower.

Besides its regular reference services the library has facilities for reproduction of the library's material in photostat, microfilm, photographs, and lantern slides. Bibliographies are compiled or checked from original sources, and abstracts and translations are made from French, German, or Spanish. Names of translators will be supplied for other languages. The library also edits manuscripts for publication. The rare book and history rooms are open to fellows and the general public Monday through Friday, 9 a. m. to 5 p. m., and closed to everyone evenings, Saturdays, and holidays. The rare books themselves do not circulate, but many of the reference works, histories, and bibliographies may be borrowed.

NORTH CAROLINA

Southern Pediatric Seminar.—This annual seminar will be held at Saluda July 16-28 and will be followed by a graduate summer course in obstetrics and gynecology July 30-Aug. 4. The seminar is especially for general practitioners. The registration fee is $25 for the graduate course and $40 for the pediatric course or $50 for the combined courses. Advance registration is necessary.

Dr. Womack to Head Department of Surgery.—Dr. Nathan A. Womack, head of the department of surgery at the University of Iowa, Iowa City, has accepted the position as professor and head of the department of surgery at the University of North Carolina School of Medicine and will take up his duties in Chapel Hill in the late summer. Before heading the department of surgery at the University of Iowa, he was professor of clinical surgery at Washington University School of Medicine, St. Louis.

OKLAHOMA

Dr. Howard Joins Institute Staff.—Dr. R. Palmer Howard, formerly demonstrator in medicine at McGill University Faculty of Medicine, Montreal, Canada, also in charge of the endocrine clinic and laboratory of the Montreal General Hospital, has been appointed a member of the staff of the Oklahoma Medical Research Institute and Hospital, Oklahoma City. The institute and hospital has an academic affiliation with the University of Oklahoma School of Medicine. Dr. Howard will continue his research in endocrinology. He will be associated with Dr. Edward C. Reifenstein Jr., director of the institute and head of the section on metabolic alterations, in a study of metabolic bone diseases.

Study of Geriatric Problems.—An expanding program of medical research is underway at the Oklahoma Medical Research Foundation in Oklahoma City, with initial studies in the field of geriatrics, primarily projects dealing with cancer, heart disease, arthritis, and metabolic bone ailments. Completion of a 22-bed modern hospital to make clinical material available to the research staff is expected by July. Located immediately adjacent to the foundation's principal structure, the Research Hospital is being built at a cost of $225,000. Dr. Leonard P. Eliel, research scientist now with the Sloan-Kettering Institute of New York, will join the foundation in July to conduct studies dealing with fluid balance as it relates to the use of cortisone and corticotrophin (ACTH). Dr. Eliel will be the sixth permanent member of the foundation research staff.

PENNSYLVANIA

Society News.—The Pennsylvania Academy of Ophthalmology and Otolaryngology held its annual meeting May 3-6 in Wernersville. In addition to formal presentations, four roundtable discussions and 12 study clubs were held. The meeting was attended by specialists from all parts of the state and from surrounding states. Among the officers of the organization for the ensuing year are: Dr. Matthew S. Ersner, Philadelphia, president; Dr. Samuel T. Buckman, Wilkes-Barre, president-elect; Dr. Daniel S. DeStio, Pittsburgh, secretary, and Dr. Bruce A. Grove, York, treasurer.——The Pennsylvania Radiological Society May 18-20 elected officers for the coming year. Dr. Maurice Goldsmith was chosen president and Dr. William V. Dzurek, Pottsville, president-elect.

Philadelphia

Thirty-Nine New Women Doctors.—Commencement at the Woman's Medical College, now in its 101st year, was held on June 15, when 39 women received the degree of doctor of medicine. The honorary degree of doctor of science was conferred on Dr. Helen B. Taussig, associate professor of pediatrics, Johns Hopkins University School of Medicine, Baltimore, and on Mr. John M. Russell, vice president and executive director of the John and Mary Markle Foundation, who gave the commencement address. His subect was "On Being Dissatisfied." Dr. Louise Pearce, Belle Mead, N. J., presided at the exercises. Dean Marion Fay presented the candidates for their degrees. Dr. L. Kraeer Ferguson, professor of surgery, presented the hoods for investiture and the Hippocratic Oath was administered by Dr. Mollie A. Geiss, professor of pathology. Another highlight of the commencement was the awarding of medals to 10 women who graduated 50 years ago by the alumnae association president, Dr. Mary R. Curcio. Four were present in person to receive awards: Dr. Hannah Frances Bartlett Tyson, Leonia, N. J., Dr. Elizabeth Comstock, Arcadia, Wis., Dr. Mary Riggs Noble, Bowmansdale, Pa., and Dr. Elsie Treichler-Reedy of Philadelphia. The following prizes were awarded: the President's Prize for the highest average for four years to Mia Parsonnet; the Dean's Prize for the highest average for the fourth year to Elsie M. Tytla; the Professor of Surgery Prize for the highest average in general surgery to Edith J. Miller; the Department of Medicine Prize for the highest average in medicine to Jean Stuart Vogt; the Elise L'Esperance Prize of $100 "for work in the cancer field by graduate or undergraduate students," awarded to Edithe J. Miller, with honorable mention to Fae M. Adams, and the Oncology Award to Renate Leo.

SOUTH DAKOTA

Medical Students to Serve Clerkships.—Thirty-one second-year students at the University of South Dakota School of Medicine, Vermillion, will serve one month as clinical clerks with doctors in South Dakota starting June 25. This is the third year these clerkships have been offered sophomore students. The program has met with success. Physicians in all parts of the state will act as preceptors. The clerkships will end in time for the students to prepare for entering four-year schools of medicine in the fall for their junior and senior years.

TEXAS

New Fellowships.—The Ferris and Florence Smith Foundation for Plastic Surgical Research, Grand Rapids, Mich., has established a fellowship at the University of Texas Medical Branch, Galveston, for work in the Tissue Culture Laboratory under the direction of Charles M. Pomerat, Ph.D. The fellowship is currently being held by Dr. Jorge Gonzalez Ramirez from the laboratory of Dr. I. Costero of Mexico City.

Postgraduate Medical Assembly.—The annual meeting of the Postgraduate Medical Assembly of South Texas will be held July 23-25 at the Shamrock Hotel in Houston. Summer rates will prevail. Medical motion pictures and scientific and technical exhibits will be shown. Twenty-three out-of-state guest speakers are on the program. Those in the medical section include: Drs. Thaddeus S. Danowski, Pittsburgh; Garfield G. Duncan, Philadelphia; Cyrus C. Sturgis, Ann Arbor, Mich.; Robert B. Lawson, Winston-Salem, N. C.; Alan G. Cazort, Little Rock, Ark.; Lealdes M. Eaton, Rochester, Minn.; Earl D. Osborne, Buffalo, and William B. Wartman, Chicago. Those in the surgical section include: Drs. Harvey S. Allen, and M. Edward Davis, Chicago; Alvin J. Ingram, Memphis; John H. Mulholland, New York; Morris J. Nicholson, Boston; William P. Longmire Jr., Los Angeles; George C. Prather, Boston, and Herbert E. Schmitz, Chicago. Those in the EENT section include: Mr. J. C. Copeland, Chicago; Dr. Brittain F. Payne, Dr. Samuel Fomon, and Dr. William W. Morrison, New York.

UTAH

University News.—The University of Utah, Salt Lake City, is negotiating with the Atomic Energy Commission for construction of radiobiology laboratories costing approximately $100,000 in the new medical center. A diversified program of research on the effects of radiation as it is of particular concern to the AEC will be carried out in these laboratories.

Dr. Mark Nickerson, Ph.D., is leaving the research faculty of the University of Utah College of Medicine to assume an appointment as associate professor of pharmacology at the University of Michigan, Ann Arbor. Dr. Hyrum L. Marshall, formerly professor of public health and preventive medicine and acting dean until the arrival of Dean Bowers last fall, has been appointed medical director for the trust territory islands of the Pacific, with headquarters in Hawaii.

VERMONT

Council to be Guests of Bar Association.—The board of managers of the Vermont Bar Association has invited the Council of the Vermont State Medical Society to meet with them on June 24 at 12:30 p. m. at the Long Trail Lodge, Cherburne Pass. Matters of mutual interest will be discussed.

VIRGINIA

Cancer Award.—Dr. George Cooper Jr., associate professor of roentgenology, University of Virginia, was awarded the American Cancer Society's 1951 medal for Virginia May 18 in recognition of his contributions to the control of cancer. Dr. Cooper is medical and scientific director and a member of the board of trustees of the Virginia Division, American Cancer Society, and chairman of the cancer committee of the Medical Society of Virginia. Last year's American Cancer Society Award for Virginia was presented to Dr. Edwin P. Lehman, professor of surgery and gynecology at the University of Virginia.

Dr. Fitz-Hugh to Succeed Dr. Woodward.—Dr. Fletcher D. Woodward, professor of otolaryngology at the University of Virginia, retires as chairman of the school of otolaryngology July 1 after 26 years of service but will remain active in the teaching and clinical programs. Dr. G. Slaughter Fitz-Hugh, clinical assistant professor of otolaryngology, will succeed Dr. Woodward as chairman of the department. Dr. Woodward is currently directing the organization of the new Virginia Hearing Foundation at the university. His co-director is James M. Mullendore, director of the Speech and Hearing Center. The foundation will offer a training center for specialists in diseases of the ear and will provide a complete diagnostic clinic. Plans include a full-time traveling clinic to conduct hearing tests.

WASHINGTON

Foundation Appointments.—Pinel Foundation, Inc., a Seattle nonprofit organization for psychiatric treatment, training, and research, announces the appointment of the following doctors to augment its staff: Morton E. Bassan, Norman Chivers, Charles Gable, Gert Heilbrunn, and Charles A. Mangham.

ALASKA

Three Floating Clinics.—Three floating clinics of the Alaska Department of Health are again taking health programs to remote communities where other medical facilities are unavailable. The barge *M/V Yukon Health* that wintered in the Yukon River ice at Holy Cross will work down to the mouth of the river this season. Dr. Catherine Nelson, Seattle, is in charge of the medical work aboard. The staff also includes a dentist and a dental technician. The *M/V Health*, which has been in operation for the past two years, was completely overhauled in Seattle and arrived in Juneau in mid-May en route to northern waters. Its base has been changed from Kodiak to Seward, and its work for the season is scheduled between Egegik and the mouth of the Yukon River. Dr. Hazel I. Blair, Juneau, is physician in charge. The *M/S Hygiene* will operate this year in southeastern Alaska waters under the direction of Dr. Lawrence Rose.

GENERAL

Society Election.—At the annual meeting of the American Association of Genito-Urinary Surgeons held May 16-18 the following officers were elected: Dr. Charles C. Higgins, Cleveland, president; Dr. Albert J. Scholl, Los Angeles, vice president, and Dr. Norris J. Heckel, Chicago, secretary-treasurer.

Personal.—Dr. Theodore K. Klumpp, president of Winthrop-Stearns, Inc., New York, has been elected to the board of directors of the U. S. Committee of the World Medical Association. The board of directors has been increased to 40 members.

Section Meeting of Urological Association.—The western section of the American Urological Association will hold its annual meeting in Sun Valley June 25-28. There will be special lectures by Dr. George F. Cahill, New York, and Dr. Elmer Hess, Erie, Pa., president of the American Urological Association. Dr. T. Leon Howard, Denver, will be in charge of the roundtable session Tuesday afternoon.

WHO Aids Earthquake Victims.—Medical supplies were flown May 16 to El Salvador from Washington, D. C., by the World Health Organization's regional office for victims of the recent earthquakes that struck several towns and injured thousands of persons. The Pan American Sanitary Bureau sent 4,000 capsules of chloromycetin, 4,000 capsules of aureomycin, and 225 pounds of chlorinated lime to treat victims and to purify water as a preventive measure against epidemics.

Hospital Library Meeting.—The hospital libraries division of the American Library Association will meet at the Palmer House and Stevens Hotel in Chicago July 8-14. At the luncheon meeting July 11 Dr. Herman N. Bundesen, president of the board of health, Chicago, will speak on "Civil Defense Planning in Chicago Hospitals." Tours of the libraries of the Hines Veterans Administration Hospital and the Bacon Library of the American Hospital Association are included in the program.

Serum Hepatitis in Portland and Boston.—It has been reported to the U. S. Public Health Service that 14 cases of serum hepatitis occurred in Portland, Maine, during the past 10 months in persons who had received thrombin of human origin. Another group of persons treated with the same product was found in Boston. The incubation periods in the Portland group varied from 90 to 105 days. Thrombin of human origin has been recalled from all distributing centers and consignees.

Sugar Research Foundation Grants.—This foundation has given the Harvard School of Public Health a grant-in-aid for the study of sugar as the base for emergency rations for civilian populations. Six other laboratories sharing in the $146,835 appropriated for research this year by the foundation are at Emory University, Ga.; University of Pennsylvania School of Medicine and Jefferson Medical College, Philadelphia; Boston City Hospital; California Foods Research Institute, and Belmont Chemical Sales Development Co., Chicago.

Muscular Dystrophy Foundation Committee.—Dr. Dereck E. Denny-Brown, James Jackson Putnam professor of neurology at Harvard Medical School, Boston, has accepted chairmanship of the committee on research of the National Muscular

Dystrophy Foundation, Inc. Other science investigators who have been named to this board are Dr. Ralph W. Gerard, Chicago; Dr. Samuel J. Morgulis, New York; Dr. Hebbel E. Hoff, Houston, Texas, and Dr. Johannes M. Nielsen, Los Angeles. The foundation welcomes requests for grants for research in dystrophy, and the new committee will evaluate such requests.

***Foundation* Awards Cancer Funds.**—The Black-Stevenson Cancer Foundation has awarded about $750,000 each to the Presbyterian Hospital in Newark, N. J., and the Memorial Center for Cancer and Allied Diseases in New York. The institutions were selected from among more than 5,000 that had applied for donations during the last five years. The grants were made as 20-year endowments, with the institutions permitted to expend not more than 10 per cent of the principal each year if they elect to do so. Each hospital will set up separate funds to be called the Black-Stevenson Memorial Fund, which will be applied "for the care and treatment, preventive and remedial, of needy persons afflicted or threatened with cancer."

***International Pathology* Congress.**—The International Congress of Clinical Pathology will be held in London July 16 to 20, with offices to be housed in the University College on Gower St. The congress is under the auspices of the International Society of Clinical Pathology, of which Dr. S. C. Dyke, Wolverhampton, England, is president. Sir Lionel Whitby, Cambridge, will preside. The scientific program will begin July 17 with daily sessions on microbiology, morbid anatomy, chemical pathology, and hematology. The registration fee is 2£ ($5.60). Inquiries should be addressed to the secretary-treasurer, Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London, W.9.

U. S. Companies to Produce Drugs in South America.—Fontoura-Wyeth, S. A., Brazil, an affiliate of Wyeth Incorporated, will construct a five-story laboratory in Sao Paulo, Brazil, for production of various penicillin salts and the conversion of penicillin into various forms suitable for medical and veterinary use. The laboratory will cost in excess of 2 million dollars.

The Armour Laboratories of Chicago will shortly open a new four-story plant in Buenos Aires, Argentina, to tap new sources of raw material to relieve a potential shortage of insulin and increase supplies of ACTH and trypsin. The plant's production will go first to supply the needs of Argentina. The Argentine government has agreed to permit the export of the surplus, about 80 per cent.

Space Medicine Society.—This society was organized by doctors attending the recent meeting of the Aero Medical Association in Denver. Space medicine is a new branch of medical science developed in the last few years as jet planes and rocket-powered aircraft have approached the regions outside the earth's atmosphere. Aviators must deal in those regions with such unfamiliar problems as bombardment of their aircraft by cosmic rays and gravity-free flight at high speeds when their bodies will have no weight. At this meeting Col. Paul A. Campbell, director of research at the Air Force School of Aviation Medicine, Randolph Field, Texas, was chosen chairman of the society, and Dr. Hubertus Strughold, head of the department of space medicine at this school, was named secretary. Capt. Ashton Graybeil, director of research, Naval Aviation Medical School, Pensacola, Fla., was appointed chairman of the membership committee.

Pan American Sanitary Bureau Budget.—A budget of $1,943,681 for the use of the Pan American Sanitary Bureau during 1952 has been approved by the executive committee, which ended its 13th meeting May 1 in Washington, D. C. The budget will be presented for final action to the organization's directing council meeting in Washington next autumn.

In view of the delays in the receipt of contributions from some of the 21 member governments of the organization hampering the public health programs undertaken by the bureau, the executive committee resolved to approve the procedure whereby the director of the bureau sends monthly notifications to the health authorities of the members, as well as to the ministries of foreign affairs, through the Organization of American States as to the status of the bureau's quota contributions. The 1952 budget will permit under limits the continuation of the bureau's activities. In the light of the present financial situation, it was decided not to open a proposed field office in the southern part of South America. However, the field offices in Lima, Peru, and Rio de Janeiro, Brazil, will be enlarged to take care of the field work in the southern areas of the continent. The field offices in Guatemala and El Paso, Texas, will continue, and a new field office is planned for Mexico City.

Multiple Sclerosis in New Orleans and Winnipeg.—A comparative investigation of all known multiple sclerosis cases in New Orleans and Winnipeg, Manitoba, Canada, has been launched as a result of grants made by the National Multiple Sclerosis Society, New York, and the Ministry of Health and Welfare of Canada. The society's grant of $4,050 has been awarded to Dr. Robert G. Heath of the Tulane University of Louisiana School of Medicine, New Orleans, while a grant of $7,990 supporting the Winnipeg study has been made by the Ministry of Health and Welfare of Canada to Dr. Maxwell Bowman, University of Manitoba Faculty of Medicine. The investigation will be based on the results of statistical surveys already conducted by the universities for the National Multiple Sclerosis Society, a part of a national study under the direction of Dr. Leonard T. Kurland, recently appointed epidemiologist of the National Institute of Mental Health, United States Public Health Service. The national study aims to determine the prevalence of multiple sclerosis as well as the effect of climate and other factors on its incidence and course. Studies completed show that multiple sclerosis is three and one-half times as frequent in Winnipeg as in New Orleans. Although geographic differences in prevalence have been cited previously, the new project is the first intensive investigation that aims primarily to ascertain why such a difference exists. This investigation represents the 13th research project supported by the National Multiple Sclerosis Society in little more than four years of existence.

Fellowships in Child Psychiatry.—These fellowships offering specialized training in child guidance clinic psychiatry are still available for September, 1951, in a number of member clinics of the American Association of Psychiatric Clinics for Children. At the completion of training, openings are available in all parts of the country. Fellows receive instructions and supervision in diagnostic and therapeutic techniques with children, in the utilization of the integrated services of the psychiatric clinic team, and in the coordination of clinic effort with the work of health, welfare, and educational agencies in the community. Most of the clinics plan for a two-year training period, although a few still accept one-year fellows, and a few others will consider giving one-year training in special cases. Fellowship stipends are usually $3,000 for the first year and $3,600 for the second. Funds come from the U. S. Public Health Service, from the clinics doing the training, and in some cases from clinics or communities paying for the training of psychiatrists promising to work in these communities. The office of the American Association of Psychiatric Clinics for Children gives information and assistance to applicants. Application may be made through this office or directly to the individual clinics, but in all cases acceptance is by the training centers. In practically all instances the work at these clinics has been credited by the American Board of Psychiatry and Neurology for a third year of training and for an additional year of experience. For information address Miss Mary C. Bentley, Executive Assistant, American Association of Psychiatric Clinics for Children, 1790 Broadway, Room 916, New York 19.

CORRECTION

Intravenous Use of Alcohol.—In The Jounal, May 5, 1951, page 22, right hand column, 24th line from the bottom of the page, the sentence beginning "One hundred cubic centimeters of 5 per cent alcohol" should read "One thousand cubic centimeters of 5 per cent alcohol."

MEETINGS

American Electroencephalographic Society, Hotel Claridge, Atlantic City, June 16-17. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hearing Society, Palmer House, Chicago, June 29. Mrs. Frances E. Lee, 817 Fourteenth St. N.W., Washington 5, D. C., Secretary.

American Neurological Association, Atlantic City, June 18-20. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Orthopedic Association, The Greenbrier, White Sulphur Springs, W. Va., June 20-23. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

Great Falls Medical-Surgical Conference, Great Falls, Montana, June 25-26. Dr. William E. Sullens, Box 1066, Great Falls, Chairman.

Idaho State Medical Association, Sun Valley, June 17-20. Dr. Robert S. McKean, 305 Sun Building, Boise, Secretary.

Maine Medical Association, Poland Spring House, Poland Spring, June 17-19. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Medical Library Association, Denver, June 28-30. Miss Caroline Riechers, Rush Medical College Library, 1758 W. Harrison St., Chicago 12, Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Society of Biological Psychiatry, Claridge Hotel, Atlantic City, June 17. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles 17, Secretary.

West Virginia State Medical Association, The Greenbrier, White Sulphur Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6^e, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress of Gynecology, Maison de la Chimie, Centre Marcellin, Paris, France, June 23-29. Dr. Maurice Fabre, 1, rue Jules-Lefebvre, Paris 9, General Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19.

International Congress of Military Medicine and Pharmacy, Paris, France, June 17-23. Physician General Dutrey, 8, bis, rue de Recollets, Paris 10, Secretary General.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physical Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 26-28. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Arizona:* *Examination.* Phoenix, July 17-19. *Reciprocity.* Phoenix, July 21. Sec., Dr. J. H. Patterson, 316 W. McDowell Road, Phoenix.

California: *Written.* San Francisco, June 25-28 and Aug. 20-23. *Oral.* San Francisco, June 23 and Los Angeles, August 18. *Oral and Clinical Examination for Foreign Medical School Graduates.* San Francisco, June 24 and Los Angeles, August 19. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* *Examination.* Denver, June 18-20. *Reciprocity.* Denver, July 10. Sec., Dr. George H. Gillen, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, July 10-11. Sec. to the Board, Dr. Creighton Barker, 160 St. Ronan St., Hartford. *Homeopathic.* Derby, July 11-12. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 19. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

Florida:* *Examination.* Jacksonville, June 24-26. Sec., Dr. Homer L. Pearson, 701 DuPont Bldg., Miami.

Georgia: Atlanta, June. Augusta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Hawaii: *Examination.* Honolulu, July 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, July 9-11. Sec., Mr. Armand L. Bird, 305 Sun Bldg., Boise.

Illinois: Chicago, June 26-28. Supt. of Regis., Mr. Charles F. Kervin, Capitol Bldg., Springfield.

Maine: Augusta, July 10-11. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Massachusetts: *Examination.* Boston, July 10-13. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Mississippi: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Jackson 113.

Nebraska: * June 1951. Director, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln.

Nevada:* Carson City, August 6. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: Concord, Sept. 12-13. Sec., Dr. John Samuel Wheeler, Room 107 State House, Concord.

New Mexico:* Santa Fe, Oct. 8-9. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: Albany, Buffalo, New York and Syracuse, June 26-29. Sec., Dr. Jacob L. Lochner, Jr., 23 S. Pearl St., Albany 7.

North Dakota: Grand Forks, July 4-7. Sec., Dr. C. J. Glaspel, Grafton.

Oregon:* *Examination.* Portland, June 21-23. Special examination for physicians who have orders to report for military service about July 1. *Examination.* Portland, July 5-7. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July 10-13. Acting Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, Sept. 4. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

Rhode Island:* *Examination.* Providence, July 5-6. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, June 25-27. *Reciprocity.* Columbia, April 2 and May 15. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: Rapid City, July 17-18. Sec., Dr. Clarence E. Sherwood, 109 Center St., West, Madison.

Utah: Salt Lake City, July 11-13. Asst. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Washington:* Seattle, July 16-18. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

West Virginia: Charleston, July 9-11. Sec., Dr. N. H. Dyer, Capitol Bldg., Charleston 5.

Wisconsin:* Milwaukee, July 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: *Examination.* Cheyenne, June 4. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, August. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

District of Columbia: *Examination.* Washington, Oct. 22-23. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Iowa: *Examination.* Des Moines, July 10. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Nevada: *Examination.* Reno, July 3. Sec., Mr. Frank Robinson, University of Nevada, Reno.

Oklahoma: Oklahoma City, Sept. 14. Sec., Dr. Frank C. Gallaher, 813 Braniff Bldg., Portland 4.

Oregon: *Examination.* Portland, Sept. 8 and Dec. 1. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

Tennessee: *Examination.* Memphis, July 5-6. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Texas: *Examination.* Austin, October. Chief Clerk, Mr. B. H. Kirk, 306 Nalle Bldg., Austin.

Washington: *Examination.* Seattle, July 11-12. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

---

* Basic Science Certificate required.

DEATHS

Crowell, Bowman Corning ⊕ Chicago; born in Yarmouth, N. S., Canada, Jan. 10, 1879; McGill University Faculty of Medicine, Montreal, 1904; instructor in pathology, University and Bellevue Hospital Medical College, New York, 1907-1911; associate professor of pathology and bacteriology at the University of the Philippines College of Medicine and Surgery and chief of the department, 1912-1914; professor and chief of department, 1914-1918, and director, 1916-1918, Graduate School of Tropical Medicine and Public Health; professor of pathology at the Medical College of the State of South Carolina, Charleston, 1922-1923, and of Jefferson Medical College, Philadelphia, 1923-1926; lecturer in pathology at Northwestern University Medical School, 1927-1949; pathologist, Bureau of Science in Manila, P. I., 1911-1915; chief of service, department of pathology, Oswaldo Cruz Institute, Rio de Janeiro, Brazil, 1918-1922; member of the board of directors of the American Cancer Society, which on Oct. 28, 1949, awarded him its first annual medal "in recognition of his outstanding contributions to the control of cancer"; member of the board of directors of the Gorgas Memorial Institute and the National Malaria Commission; president of the Philippine Island Medical Association in 1918; member of the International Association of Medical Museums, American Association for the Advancement of Science, Chicago Pathological Society, American Association for Cancer Research, Institute of Medicine of Chicago, and Chicago Academy of Sciences; honorary member, the Brazilian Academy of Medicine and the American Society of Clinical Pathologists; from 1923 to 1926 pathologist and director of laboratories, Jefferson Hospital, and visiting pathologist at Philadelphia General Hospital, both in Philadelphia; since retirement on Nov. 15, 1949, served as associate director emeritus at the American College of Surgeons, where he was associate director and director of the department of clinical research from 1926 to 1949; died in Clermont, Fla., April 26, aged 72, of coronary occlusion.

Lynch, Jerome Morley ⊕ Carmel, Calif.; born in Ireland Jan. 11, 1869; Rush Medical College, Chicago, 1895; an Associate Fellow of the American Medical Association; member of the Medical Society of the State of New York; honorary member and fellow of the Royal Society of Medicine, London; member of the American Proctologic Society, of which he was past president, and the American Gastro-Enterological Association; fellow of the American College of Surgeons; member of the Military Order of Foreign Wars; specialist certified by the American Board of Surgery and the American Board of Proctology; at one time practiced in New York; served as professor of proctology at New York Polyclinic Medical School and Hospital; served during World War I; formerly consulting surgeon, Neurological Institute and New York State Psychiatric Institute, Beekman-Downtown Hospital, New York, General Hospital, Saranac Lake, N. Y., St. John's Riverside Hospital, Yonkers, N. Y., and St. Mary's Hospital in Hoboken, N. J.; author of "Diseases of Rectum and Colon and Their Surgical Treatment," 1914, and "Know Your Patient," 1943; co-author of "Tumors of Colon and Rectum, Their Pathology, Diagnosis and Treatment," 1925; died April 22, aged 82.

Taft, Robert Burbidge ⊕ Charleston, S. C.; born in Charleston Sept. 20, 1899; Medical College of the State of South Carolina, Charleston, 1923; professor of radiology and electrotherapy at his alma mater; specialist certified by the American Board of Radiology; served during World War I; past president of the South Carolina X-Ray Society; member and formerly chairman of the committee for use and rental of radium of the American Roentgen Ray Society, which awarded him silver medals for his exhibits in 1936 and 1942; member of the South Carolina Academy of Science, which in 1929 awarded him the Jefferson Medal; member of the Radiological Society of North America, of which he had been second vice president and member of the committee on standardization of x-ray, American College of Radiology, and the American Radium Society; member of the board of commissioners of the Charleston Museum; a licensed transport air pilot and member of the board of governors of Charleston Airport; affiliated with Baker Memorial Sanatorium; author, "Radium Lost and Found," published in 1938, and a second edition in 1946; technical editor of the *American Journal of Roentgenology;* died April 16, aged 51.

Ransohoff, Nicholas Sigmund ⊕ New York; born in Salt Lake City Oct. 18, 1895; Columbia University College of Physicians and Surgeons, New York, 1919; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; served as president of the New Jersey Orthopedic Society; fellow of the American College of Surgeons; associate orthopedic surgeon, Hospital for Joint Diseases in New York; orthopedic surgeon and director of fracture service, Monmouth Memorial Hospital, Long Branch; orthopedic surgeon, Riverview Hospital, Red Bank, N. J.; consulting orthopedic surgeon, Paul Kimball Hospital in Lakewood, Fitkin Memorial Hospital in Neptune, Children's Country Home in Westfield, and Betty Bacharach Home for Afflicted Children in Longport; died in Long Branch, N. J., April 25, aged 55, of coronary thrombosis and arteriosclerosis.

Shaklee, Alfred Ogle, St. Louis; born in Middle Creek, Ohio, Oct. 3, 1865; St. Louis University School of Medicine, 1908; associate professor of pharmacology at his alma mater; associate professor of pharmacology at the University of the Philippines College of Medicine in Manila from 1910 to 1913 and the University of Illinois College of Medicine in Chicago from 1914 to 1916; professor of physiology and biochemistry at Fordham University School of Medicine in New York from 1916 to 1918; associate professor of physiology at the University of Texas Department of Medicine in Galveston from 1918 to 1921; member of the American Association for the Advancement of Science; died in Desloge Hospital April 19, aged 85, of cancer.

Aldrich, Addison D. ⊕ Houghton, Mich.; born in 1879; Saginaw Valley Medical College, Saginaw, 1903; Detroit College of Medicine, 1910; past president of the Houghton-Baraga-Keweenaw Counties Medical Society; formerly a member of the state health council, a member of the advisory council of the state board of health, and director of the Houghton-Keweenaw-Baraga health department; served as health officer and physician for the village of Houghton, and for Portage, Elm River, and Osceola townships for many years; on the staff of St. Joseph's Hospital in Hancock; active in the Boy Scouts of America, receiving the honorary Silver Beaver Award in 1936; died April 21, aged 72, of fibrosarcoma of the lungs.

Partch, Wallace Taylor ⊕ Oakland, Calif.; born in Shanghai, China, Feb. 16, 1899; Rush Medical College, Chicago, 1926; specialist certified by the American Board of Internal Medicine; an associate member of the American College of Physicians; entered the Mayo Foundation as a fellow in medicine in April, 1927, and left the Mayo Foundation in April, 1930, at which time he went to the Welborn Hospital Clinic, Evansville, Ind., where he remained until January, 1932; served at Carle Hospital Clinic in Urbana, Ill., for about a year; on the staffs of the Alameda County, Peralta, Berkeley General, and Berkeley Alta Bates hospitals; died April 4, aged 52, of mesothelioma.

Baum, Harry Lester ⊕ Denver; born in Shelbyville, Ill., in 1887; University of Pennsylvania School of Medicine, Philadelphia, 1910; specialist certified by the American Board of Otolaryngology; formerly assistant professor of otolaryngology at the University of Colorado School of Medicine; member of the American Academy of Ophthalmology and Otolaryngology, Pacific Coast Oto-Ophthalmological Society, and the American Broncho-Esophagological Association; served on the staff of Children's and Presbyterian hospitals; died March 25, aged 63, of coronary occlusion and malignant hypertension.

⊕ Indicates Fellow of the American Medical Association.

Adams, John Robert, Fort Wayne, Ind.; Ohio Medical University, Columbus, 1905; member of the American Medical Association; died in St. Joseph Hospital Feb. 26, aged 75, of cerebral hemorrhage and arteriosclerosis.

Allison, Blake Seymour ⊕ Long Beach, Calif.; Lincoln Medical College of Cotner University, Lincoln, Neb., 1906; died April 6, aged 74, of carcinoma of the cecum.

Anderson, John Burton, Vincennes, Ind.; Barnes Medical College, St. Louis, 1899; died in Hillcrest Tuberculosis Hospital recently, aged 78, of pulmonary tuberculosis.

Baker, Frank Kline ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1890; died April 16, aged 88.

Bloomington, Frances E. Drake, Chicago; Hering Medical College, Chicago, 1900; died in Park Ridge, Ill., April 17, aged 96.

Bradish, Jay Durkee ⊕ New London, Ohio; Ohio State University College of Medicine, Columbus, 1924; past president of the Huron County Medical Society; served during World War I; for many years county coroner; on the staffs of Samaritan Hospital in Ashland and New London Hospital; at one time epidemiologist for the Connecticut State Department of Health; died April 21, aged 56, of injuries received in an automobile accident.

Breitzer, Constantine, Brooklyn; Long Island College Hospital, Brooklyn, 1907; died in Kings County Hospital recently, aged 74.

Brown, William Frank, Keokuk, Iowa; Jefferson Medical College of Philadelphia, 1905; served during World War I; died March 18, aged 67, of coronary thrombosis and cardiorenal vascular disease.

Cail, John Calvin Jr., Sylvania, Ga.; University of Georgia School of Medicine, Augusta, 1907; served during World War I; formerly a member of the city council and a state senator; awarded the Silver Beaver for his work with the Boy Scouts of America; died March 27, aged 64, of hypertensive cardiovascular disease with decompensation.

Carpenter, George Lansing, Wrens, Ga.; University of Georgia School of Medicine, Augusta, 1909; member of the American Medical Association; died March 28, aged 66, of cerebral thrombosis and arteriosclerosis.

Chapman, Arthur William, Glens Falls, N. Y.; University of Vermont College of Medicine, Burlington, 1907; member of the American Medical Association; fellow of the American Academy of Pediatrics; past president of the Glens Falls Academy of Medicine; specialist certified by the American Board of Pediatrics; president of the staff of Glens Falls Hospital, where he died April 10, aged 69, of carcinoma of the prostate with generalized metastases.

Clapp, Fred Raymond ⊕ South Bend, Ind.; Rush Medical College, Chicago, 1903; affiliated with Memorial Hospital, where he died April 28, aged 71, of carcinoma of the lung.

Cohenour, Leo Bertram ⊕ Albuquerque, N. M.; University of Colorado School of Medicine, Denver, 1918; served during World War I; in charge of procurement and assignment for the medical corps of the Army in New Mexico during World War II; for 18 years secretary of the New Mexico Medical Society; fellow of the American College of Surgeons; on the staff of Southwestern Presbyterian Sanatorium; died April 25, aged 59, of heart disease.

Craig, Edwin M., Norwood, Ohio; Miami Medical College, Cincinnati, 1906; police and fire surgeon; died April 10, aged 80, of arteriosclerotic heart disease.

Da Costa, Samuel N., Forest Park, Ill.; Chicago College of Medicine and Surgery, 1913; died in Oak Park April 30, aged 78, of pneumonia.

Daugherty, Thomas E., Baltimore; Baltimore Medical College, 1898; died April 22, aged 78, of bronchopneumonia.

Dolnick, Max A., Chicago; Chicago College of Medicine and Surgery, 1917; died April 19, aged 66, of coronary thrombosis.

Farthing, Charles Hamilton, Meeker, Colo.; St. Louis University School of Medicine, 1905; member of the American Medical Association; died in St. Mary's Hospital, Grand Junction, April 15, aged 72, of carcinoma of the prostate.

Gerow, James Wiggins, Reno, Nev.; California Medical College, San Francisco, 1902; died in St. Mary's Hospital April 8, aged 71, of heart disease and hypertension.

Gregg, Frank Benham, Wellington, Ohio; Miami Medical College, Cincinnati, 1892; served during World War I; died April 6, aged 85.

Gros, Hubert ⊕ Delphi, Ind.; Indiana University School of Medicine, Indianapolis, 1928; served during World War II; city health officer; served as county coroner; associate staff member, St. Elizabeth Hospital in Lafayette, where he died April 1, aged 47, of chronic cholecystitis and subhepatic biliary abscess.

Harpst, Howard Henry ⊕ Toledo, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1921; affiliated with Toledo Hospital, where he died April 1, aged 56, of chronic nephritis.

Hartz, William Harry, North Belle Vernon, Pa.; University of Pittsburgh School of Medicine, 1942; member of the American Medical Association; associated with Gemmill Hospital in Monessen; died in Miami, Fla., April 2, aged 34, of rheumatic heart disease.

Horigan, Joseph Aschwanden, Kansas City, Mo.; Columbian University Medical Department, Washington, D. C., 1888; member of the American Medical Association; died April 1, aged 87, of arteriosclerotic heart disease.

Horn, Martin Irving ⊕ Bridgeport, Conn.; New York Homeopathic Medical College and Flower Hospital, New York, 1912; member of the New England Obstetrical and Gynecological Society; president of the Bridgeport Medical Association; affiliated with St. Vincent's Hospital, where he served as president of the staff; died April 1, aged 64.

Keith, Frederick Scott, Newton, Mass.; Harvard Medical School, Boston, 1892; a trustee and member of the executive board of the Newton-Wellesley Hospital, Newton Lower Falls; one of the original trustees of the Hahnemann Hospital in Boston, where he was a member of the staff; died April 5, aged 82.

Kinne, George Lyman, Holyoke, Mass.; University of Maryland School of Medicine, Baltimore, 1887; an examiner for the Metropolitan Life Insurance Company for many years; formerly affiliated with Providence Hospital and Holyoke Hospital, where he died April 4, aged 90, of myocardial failure, following a hip fracture.

Langill, Morton Howard ⊕ Worcester, Mass.; Dartmouth Medical School, Hanover, N. H., 1910; specialist certified by the American Board of Radiology; member of the New England Roentgen Ray Society and the American College of Radiology; affiliated with Belmont, Fairlawn, and Worcester City hospitals; died March 30, aged 66.

MacDonald, John Tremper ⊕ Miami, Fla.; Medico-Chirurgical College of Philadelphia, 1909; fellow of the American College of Surgeons; served during World War I; medical director, Pan American Airways, Latin American Division; a founder of Doctors Hospital in Coral Gables, where he died April 3, aged 65, of coronary thrombosis with myocardial infarction.

Macdonald, William H. ⊕ Lake Geneva, Wis.; Chicago Homeopathic Medical College, 1888; died March 17, aged 84.

Macmurphy, George Yuille, Hendersonville, N. C.; Medical College of the State of South Carolina, Charleston, 1891; died Feb. 13, aged 81, of postoperative hypostatic pneumonia and intestinal obstruction.

McPherson, William Ellsworth, Canton, Mass.; Harvard Medical School, Boston, 1891; served during World War I; died Feb. 13, aged 87, of bronchopneumonia.

Mitchell, William Harvey, Loudon, N. H.; Dartmouth Medical School, Hanover, N. H., 1893; member of the American Medical Association; died March 2, aged 82.

Morin, Jeremiah Joseph ⊕ Rochester, N. H.; University of Vermont College of Medicine, Burlington, 1909; organizer and later chief of the Frisbie Memorial Hospital; an organizer and a charter director of the Blue Shield in New Hampshire; served during World War I; died March 20, aged 65, of acute coronary occlusion.

Moyer, Jonas J., Oakland, Calif.; University of the South Medical Department, Sewanee, Tenn., 1900; died in Peralta Hospital April 4, aged 83, of acute myocardial infarction and diabetes mellitus.

Nelson, John Elisha, Chattanooga, Tenn.; University of Nashville Medical Department, 1900; member of the American Medical Association; served during World War I; died April 6, aged 74, of heart disease.

Ognibene, Daniel Francis, Long Valley, N. J.; Long Island College Hospital, Brooklyn, 1907; died in Orange Memorial Hospital, Orlando, Fla., March 22, aged 68, of congestive heart failure, coronary sclerosis, and hypertension.

Perez, Manuel Aquilino, Tampa, Fla.; Loyola University School of Medicine, Chicago, 1934; member of the American Medical Association, American Heart Association, and the Florida Pediatric Association; on the staffs of Tampa Municipal Hospital and St. Joseph's Hospital, where he died April 7, aged 41, of lymphosarcoma.

Prince, John Hayes, Piqua, Ohio; Medical College of Ohio, Cincinnati, 1909; died in Piqua Memorial Hospital March 6, aged 75, of mitral stenosis and auricular fibrillation.

Quatrano, Emanuel, Tenafly, N. J.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Naples, Italy, 1921; died in St. Mary's Hospital, Passaic, March 1, aged 53, of chronic diffuse glomerular nephritis.

Rauschenbach, Charles William ⊕ Hammond, Ind.; University of Maryland School of Medicine, Baltimore, 1912; certified by the National Board of Medical Examiners; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; affiliated with St. Margaret's Hospital, where he died Feb. 17, aged 61, of carcinomatosis.

Rey, Herman Frederic ⊕ Oxnard, Calif.; Universität Zürich Medizinische Fakultät, Zurich, Switzerland, 1921; fellow of the American College of Surgeons; affiliated with St. John's Hospital, where he died Feb. 21, aged 54, of multiple myeloma.

Rhodes, Thomas Alfred, Titusville, Fla.; Maryland Medical College, Baltimore, 1902; died March 9, aged 63, of chronic lymphoblastoma.

Rollins, Russell ⊕ Royal Center, Ind.; Indiana University School of Medicine, Indianapolis, 1936; died March 31, aged 55, of adenocarcinoma of the left parotid gland.

Runyan, William John, Glen Ridge, N. J.; Long Island College Hospital, Brooklyn, 1915; member of the American Medical Association; served during World War I; affiliated with Montclair (N. J.) Community Hospital, and the Hospital for Crippled Children in Newark; at one time superintendent of the Essex County Hospital for Contagious Diseases in Belleville; died March 5, aged 61, of coronary thrombosis.

Scanlan, Maurice ⊕ De Witt, Iowa; Rush Medical College, Chicago, 1900; died in Mercy Hospital, Davenport, April 3, aged 75.

Schottler, George Jacob, Dexter, Minn.; Rush Medical College, Chicago, 1896; member American Medical Association; died in Austin Feb. 15, aged 80, of coronary sclerosis.

Sheehan, William Coronato ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1913; fellow of the American College of Surgeons; served during World Wars I and II; on the surgical staff at Chestnut Hill Hospital; died in Palm Beach, Fla., April 12, aged 62, of coronary occlusion.

Snow, Frank Whipple ⊕ Newburyport, Mass.; Harvard Medical School, Boston, 1902; chairman of the local board of health; member of the House of Delegates of the American Medical Association from 1948 to 1951; affiliated with Anna Jaques Hospital; died in New York March 10, aged 72, of coronary occlusion.

Titsworth, George Ezra Jr., Bandana, Ky.; University of Louisville (Ky.) Medical Department, 1910; member of the American Medical Association; died recently, aged 64, of pulmonary infarct.

Turkus, Edward Newton ⊕ Vista, Calif.; Long Island College Hospital, Brooklyn, 1913; for many years member of the medical staff of St. Mary's Hospital; served as police surgeon; died April 19, aged 61, of cerebral hemorrhage.

Verser, William Walter ⊕ Harrisburg, Ark.; Memphis (Tenn.) Hospital Medical College, 1909; died March 17, aged 76.

Watkeys, Frederick W., Boston; Harvard Medical School, Boston, 1896; died Feb. 20, aged 85.

DIED WHILE IN MILITARY SERVICE

DuFrenne, Martin Fred ⊕ Colonel, M.C., U. S. Army, Middleton, Wis.; born in Middleton, Oct. 23, 1893; Marquette University School of Medicine, Milwaukee, 1916; entered the medical corps of the U. S. Army on July 1, 1920; served in Hawaii and the Philippines during World War I; graduated from the Medical Field Service School in 1923 and from the Army Medical School in 1924; during World War II was on duty as commanding officer, station hospital, Fort Myer, Va., and as surgeon, Military District of Washington, from 1942 to 1945; transferred to command of the station hospital at Fort Belvoir in 1947, where he was serving at the time of his death; was given the British Empire Medal and the Legion of Merit from our government; fellow of the American College of Surgeons; died in Walter Reed Army Hospital, Washington, D. C., Dec. 13, 1950, aged 57, of arteriosclerotic renal disease.

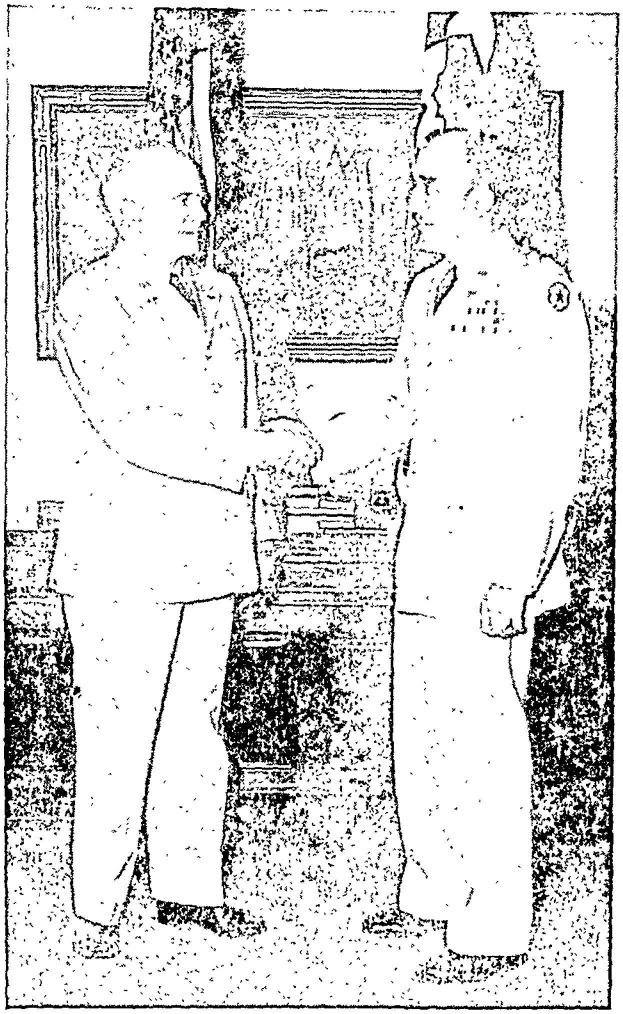
Fairless, Clyde Joseph Jr., Lieutenant Commander, M. C., U. S. Navy, Des Moines, Iowa; born in Des Moines Nov. 22, 1915; State University of Iowa College of Medicine, Iowa City, 1943; interned at the U. S. Naval Hospital in Memphis, Tenn.; commissioned a lieutenant (jg) in the medical corps of the U. S. Navy on Feb. 17, 1944; during World War II served as medical officer aboard ships operating in the South Pacific, with Marine Air Groups, and in 1946 completed instructions at the Naval Air Station in Pensacola, Fla., and was designated a Naval flight surgeon; member of the Aero Medical Association; flight surgeon aboard the Carrier *Franklin D. Roosevelt* operating in the Mediterranean; killed March 6, aged 35, when the plane in which he was a passenger crashed into the sea.

Hudson, Millard Fillmore ⊕ Medical Director, Captain, U. S. Navy, Washington, D. C.; born in Madisonville, Tenn., Dec. 17, 1889; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; specialist certified by the American Board of Internal Medicine; appointed a lieutenant (jg) in the medical corps of the regular navy in 1917; promoted to the rank of captain in 1941; served at various naval hospitals in the continental United States; aboard ships of the Pacific, Atlantic, and the Asiatic fleets; completed a course at the Naval War College in 1942; served on the Naval Retiring Board; a member of the physical disability appeal board, Navy Department, at the time of his death; for outstanding service while on the staff of the Commander Service Force Atlantic Fleet, was awarded the Letter of Commendation; died March 29, aged 61, of coronary occlusion.

GOVERNMENT SERVICES

ARMY

General Armstrong Takes Oath as Surgeon General.—Maj. Gen. George E. Armstrong was sworn in June 6 as Surgeon General of the Army at a ceremony in the office of the chief of staff of the Army. General Armstrong succeeds Maj. Gen. Raymond W. Bliss, whose retirement from the Army after 40 years' service became effective May 31. Present at the ceremony in addition to Gen. J. Lawton Collins, Army chief of staff, were Mrs. Armstrong, the general's wife; Sen. William E. Jenner of Indiana; Rep. Charles A. Halleck of Indiana; Asst. Sec. of the Army Earl D. Johnson; Vice Adm. Joel T. Boone of the Veterans Administration; Maj. Gen. Wallace H. Graham, physician to the President; Rear Adm. Lamont Pugh, Surgeon General of the Navy; Maj. Gen. Harvey G. Armstrong, Surgeon General of the Air Force; Dr. Leonard A. Scheele, Surgeon General, U. S. Public Health Service, and Dr. Joseph Lawrence, Chairman, Washington office, American Medical Association.



Maj. Gen. R. W. Bliss (left), retiring Surgeon General, and Maj. Gen. George E. Armstrong, the new Surgeon General.

General Armstrong was born in 1900 in Indiana. He received an A.B. degree in 1922 and an M.D. degree in 1925 from the University of Indiana. He enlisted as a private in the Indiana National Guard in March, 1923, and was honorably discharged as a technical sergeant in 1925 to accept a commission as a first lieutenant in the Army Reserve Corps. Following internship at Letterman General Hospital, San Francisco, he was commissioned a first lieutenant in the regular Army Medical Corps in 1926.

During World War II he served as assistant theater surgeon, China-Burma-India, followed by two years as surgeon of the China theater. He returned to the United States in 1946 to serve as chief of personnel in the Surgeon General's Office, and in 1947 he was appointed Deputy Surgeon General.

He is a fellow of the American College of Surgeons and the American Medical Association; a member of the Scottish Rite and Shrine; Phi Kappa Psi; Alpha Omega Alpha; Phi Rho Sigma, and Scabbard and Blade fraternities. He has served as a member of the House of Delegates of the American Medical Association; member of the executive council of the Association of American Medical Colleges, and member of the board of directors of the American Bureau for Medical Aid to China. Among his decorations are the Legion of Merit, the Asiatic-Pacific Campaign Medal with three bronze stars, Chinese Legion of Honor, and the Order of the Crown of Italy.

NAVY

Training for Volunteer Reserve Personnel.—The following training programs will be available to volunteer Naval Reserve medical personnel during the 1952 fiscal year:

1. A six-day course in medical aspects of special weapons and radioactive isotopes at the National Naval Medical Center, Bethesda, Md. Medical, medical service, and nurse corps officers may apply for this training.

2. A 14-day active duty training program in amphibious medicine at Little Creek, Va. Volunteer reserve medical and medical service corps officers in the grades lieutenant and lieutenant (j. g.) may apply for this training. Classes are scheduled to convene on July 9, 1951, Oct. 1, 1951, and April 7, 1952.

3. A 14-day active duty training program in malariology and mosquito control at the Naval Malaria and Mosquito Control Unit No. 1, Jacksonville, Fla. Medical and medical service corps officers may apply for this training. Classes are scheduled to convene on the first and third Wednesday of each month except January, February, and March, 1952.

4. A 14-day active duty training program for Naval Reserve ensign (HP) officers at the Naval hospital nearest the applicant's home. All officers with the rank of ensign (HP) may request this course of instruction. Applications for this training will be approved for the months of July, August, and September, 1951, only.

5. A 14-day active duty training program for enlisted volunteer Naval Reserve hospital corpsmen at the Naval hospital nearest the applicant's home.

Personal.—Rear Adm. Lamont Pugh, Surgeon General of the Navy, has been elected to membership in Phi Beta Kappa, the national scholastic fraternity. Initiation ceremonies were held at the University of Virginia, Charlottesville, June 9, following which a banquet was given by the local chapter in honor of new members.

MISCELLANEOUS

Commissioner of Food and Drugs Retires.—Paul B. Dunbar, Ph.D., commissioner of food and drugs, who has spent nearly 44 years in government service, retired at his own request May 31 and was succeeded by Charles W. Crawford, now deputy commissioner, who has been in government service 34 years and who for many years has devoted much of his time to drafting food and drug regulations and standards. Dr. Dunbar, a graduate of Gettysburg (Pa.) College, obtained his Ph.D. degree in chemistry from Johns Hopkins University. He was selected by Dr. Harvey W. Wiley as one of the original group to undertake enforcement of the Pure Food and Drugs Act of 1906.

FOREIGN LETTERS

ITALY

Q Fever.—At a session of the medical academy Filippo Pacini in Pistoja devoted to Q fever, Professor Cantieri, director of the Pistoja Hospital, discussed 11 cases observed at the hospital in addition to cases from his private practice. Diagnosis was based on complement deviation with positive titers varying from 1: 16 to 1: 4,060.

History revealed neither common living quarters among the patients nor contact with animals in the stable, herds of cattle, or animals from the slaughter-house. Only in one case was there direct contact with another patient. In another, the patient had become infected from autopsy material. The course of the disease was mild in most patients, with recovery by rapid lysis within 10 days. Hepatorenal involvement was fairly frequent with constant urobilinuria and frequent albuminuria associated with cylindruria. Sometimes fever was intermittent, with severe headache but without pulmonary manifestations. In some cases there were pulmonary manifestations, from the third to the seventh day, with scarcely any other symptoms, sometimes without any roentgenologic signs and without functional disturbances. There was no flare-up of healed tuberculous lesions and no exacerbation of an existing latent tuberculous condition. Pleuropulmonary manifestations with serous exudation, femoral phlebitis, remissions and successive relapses were rare.

Therapeutically, no response to penicillin was observed; satisfactory results were obtained with chloramphenicol and aureomycin in two cases. Professor Cantieri stressed the importance of Q fever in differential diagnosis and the importance of biologic tests as diagnostic aids. Persistent headache, sweating, type of pulmonary localization, hepatorenal involvement, and enlarged spleen are significant and require particular attention.

Dr. Mario Santi stated that doctors, especially those in rural districts, should have good knowledge of Q fever, so that patients may be treated effectively without being hospitalized. One of Dr. Santi's patients had early ulceration of the Bouveret-Duguet type in the pillars of the fauces, which until now has been considered almost pathognomonic of abdominal typhus. Another patient had a rusty sputum, which was also observed in recurrences. In many patients a peculiar condition of the tongue, ariboflavinosis, was observed on the sixth or seventh day. Epidemiologic data did not provide evidence of the probable ovine orgin of the small epidemic. The action of chloramphenicol was rapid and evident in all cases, and it constituted a useful criterion for tentative diagnosis.

Dr. Arcangioli described 10 cases of Q fever observed in Pistoja in two well-differentiated periods, from February to May and from September to November, 1950. In the first period the disease was associated with bronchopulmonary manifestations and in the second period with general infectious phenomena. The onset was acute, with severe headache, sweating, severe chills, and fever; it resolved by lysis by the 10th or 12th day. The complement deviation test was positive in all the patients. Penicillin and streptomycin gave poor therapeutic results; response to chloramphenicol was good.

Professor Terzani, Florence, recalled that the first Italian cases of Q fever were observed by Terzani and Rossi in Florence during the first months of 1948. Other cases were observed at the end of 1949 and in the first months of 1950. A definite diagnosis was made by ascertainment of complement deviation; positive results were obtained even 26 months after recovery from the disease. Forty-three patients were observed, only four of whom were women; the greatest incidence occurred in the age group 20 to 40 years; persons with various occupations, but especially farmers, physicians, medical students, and meat workers, were affected by the disease. A small epidemic occurred among the physicians and students at the Institute of Pathological Anatomy of the University of Florence after necropsy was performed in a patient who died from atypical pneumonia.

Clinical symptomatology was not uniform; even in the pulmonary manifestations great variety existed. Complement deviation was the most important laboratory test. In general, it occurred between the seventh and the tenth day; the dilution level increased usually with the progress of the disease, and the positive reaction was persistent. Professor Terzani does not believe that this demonstrates persistent infection, because relapses did not occur in any of the cases he observed. Terzani believes that complement deviation, as well as agglutination and culture, involves too much delay. There is great need for a method by which diagnosis may be established earlier.

Professor Davoli, of the University of Florence, stated that the problem of the local epidemiologic course of the disease is important. As demonstrated in Toscana, small epidemics may occur frequently without the disease becoming endemic. An epidemiologic study of Q fever was started by Professor Davoli on the request of the high commissioner of hygiene and public health.

Therapy of Testicular Ectopy.—Professor Perazzo stated that he agrees with Professor Giuliani that immobilization of the testis may result in eventual damage to the testicular parenchyma. Complete isolation of the ductus deferens, which always is sufficiently long, may be harmful. The epigastric vessels offer a certain obstacle to the placement of the testis and should be sectioned.

The small percentage (9 to 10%) of atrophy of the testicle in patients operated on is negligible. No method of orchiopexy can give 100% positive results, since there is a percentage of primarily aplastic testes.

Professor Caucci claimed never to have seen a testis descend into the scrotum with hormone therapy; he maintained that all cryptorchid patients should be operated on. The speaker answered that his observation would be of value only when it would be known in which patients it has been practiced and how it has been done. When operating on a patient 8 years old, it is not possible for one to know whether the testis would not have descended spontaneously, or with hormonal treatment, e. g., at about the age of 10. The object of his report was to establish a classification of the various forms of cryptorchism on which could be based a system of logical therapy. It is important to ascertain whether the lesion is primary or secondary. A whole scale of abnormal changes exist, which are manifested clinically under multiform aspects, and if these facts are not known, it will never be possible to institute a rational therapy.

If the patient is thoroughly studied and the therapeutic indications are exact, 100% positive results may be obtained with hormonal therapy, while no more than 80 to 90% of favorable results may be obtained after surgical therapy. The speaker does not share Professor Amantea's concept that the atrophic testis may exert an inhibitory influence on the healthy one. In fact, in the post-traumatic atrophy of a testis in youngsters, a vicarious hypertrophy of the remaining testis occurs.

Professor Romualdi expressed the belief that the endocrine glands do not exert any influence on cryptorchism and on the descent of the testis. According to Professor Perazzo, this objection does not explain the causal factor of the descent of the testis, of the pathogenesis of cryptorchism, and of the undeniable existence of degenerative characteristics in cryptorchid patients. Romualdi affirmed that the glands of internal secretion do not function in the fetus. According to Professor Perazzo, that may be true during the first weeks in which exclusively maternal hormones circulate in the fetus, but the endocrine function soon becomes activated. In fact, Wells has demonstrated corticoadrenal secretion, while Hooker and collaborators have extracted androgen from fetal testes.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Professor Polichetti reported practicing postoperative hormone therapy in his patients. The speaker replied that such therapy is always recommended in his clinic as an adjunct to surgical therapy. Androgens were used in doses of 25 to 50 mg. twice a week for direct stimulation of the gonad, which is in condition to respond to such stimulus when located in the normal site. The speaker agreed with Professor Cavina that the abdominal testis, especially in iliac retention, often is not palpable, but when operated on is well developed. In conclusion, Professor Perazzo pointed out that all the speakers agreed on the absolute necessity that the testis be brought into the scrotum at the period of puberty. Otherwise cryptorchism results in castration.

New Concepts Concerning the Great Omentum.—Professor Schiassi lectured at the Academy of Science of Ferrara on the newer concepts regarding the great omentum. According to Schiassi, the great omentum, which covers the abdominal viscera, provides thermic protection of the digestive system through the number and volume of its fat lobules and protects the intestine from compression by aponeurotic formations or hernial protrusions.

It has a fairly rich and active supply of blood, lymph, and nerves; these provide a chemotactic action which limits disease processes and diminishes their damaging effects. The circulation of the large omentum is directly related to the circulation of the viscera, especially of the liver, and the great vascularity has induced surgeons not to limit themselves, in case of extensive resection, to ligation of the main pedicle only, but always to make additional ligatures. This same vascularity, on the other hand, induced Talma to devise the surgical procedure for ascites in some cases of hepatic cirrhosis.

SWEDEN

Reliability of Radiograms.—Disquieting disclosures in the foreign medical press concerning the frequency with which radiograms are misinterpreted have made Swedish radiologists look critically at their own work. Dr. Arne Nelson, who is in charge of the Swedish State Radiography Center, has lately given an account of the precautions taken at this center to reduce mistaken interpretations of radiograms to a minimum. Every newcomer to this center has to serve a carefully graduated apprenticeship. During his first month he does nothing but follow the work of an experienced colleague. During his second month he passes judgment on only a small number of radiograms, and he does not begin to act as an independent interpreter of them until he has given satisfaction for three to four months. During this period, and during his first year and also at later intervals, his work is subjected to sampling tests, and he is usually not expected to pass judgment on more than 700 to 800 radiograms daily. Dr. Nelson admits that a substantial reduction could be made in the incidence of errors if all positive radiograms were to be judged by three instead of by two experts. However, the cost of this additional precaution would be considerable.

Psychotechnical Tests for Entrants to Medical Schools.—The recent proposal by an authoritative body to limit the number of entrants to the medical profession by subjecting them to psychotechnical tests has evoked a lively discussion on the merits of such tests in the lay and medical press. Prof. Robin Fåhræus, whose pioneer work on the erythrocyte sedimentation rate is well known, has little good to say of these tests. He believes that students can be cleverly coached to pass the tests and thus be enabled to defeat their competitors unfairly. He is also of the opinion that an applicant from the country would be handicapped in a test competition with the often better-informed city dweller. Psychotechnical testing, being still in its infancy, may vary in quality with the different experts employing it. His opinion of such testing is, indeed, so poor that he suggests the drawing of lots as a better alternative. Docent Bror Rexed, a member of the authoritative body just referred to, disagrees with much of the above criticism. He points out that, during the last 15 to 20 years, more than 200,000 applicants for admission to medical schools in the United States have undergone such tests. He does not believe in any effective short cut to the passing of such tests by coaching or cramming, and he insists that there is hardly any limit to the variations that can be made in such tests.

Dr. Bengt J. Lindberg, on the other hand, bases his criticism of such tests on the reflexion that they are quite incapable of "spotting the winner," of preserving for the medical profession those who could become its best known members. If one studies the biographies of Swedish doctors, he will find they represent every variety of personality and mental equipment from the mechanical genius and the coldly intellectual to the warm-hearted family doctor, from the artist to the statistician. It is possible that the need for such tests may be greater in the United States, with its comparatively wide range of school education, than it is in Sweden, where considerable uniformity of education is achieved throughout. The admission of students to the medical curriculum, hitherto largely depending on school records and examinations, can therefore be regulated according to comparatively uniform standards in Sweden.

Dr. Lindberg has recently suggested an alternative to psychotechnical tests—examination records and the drawing of lots. It is a system that would defer decision for or against admission to medical studies until a course and examination had been taken in certain subjects, such as statistics, psychology, and genetics. Whatever the outcome, such a course need be no waste of time, since these subjects would be useful in any case.

Legal Induction of Abortion.—The so-called abortion law of June 17, 1938, has been supplemented from time to time by certain regulations, the last of which is dated May 17, 1946. The indications for the legal induction of abortion are now clearly defined. In the larger towns in Sweden, expert advice is now available for women contemplating the induction of abortion. This problem is less easily solved in the smaller towns, but a communication on the subject in the organ of the Swedish Medical Association, *Svenska Läkartidningen*, April 13, 1951, by Dr. C. G. Tropé and a social worker, Dorrit Carlson, shows what was observed in a town with a population of about 25,000. Their observations concern the year Nov. 1, 1949-Nov. 1, 1950, during which a special department attached to a child welfare center dealt with 34 cases (21 married women and 13 unmarried, divorced, or widowed) of legal induction of abortion. The average age of the married women was comparatively high; 57% of them were between the ages of 31 and 45, whereas only 8% of the women in the second category belonged to the same age group. Of the 26 women whose request was granted, 18 were married. Hardly any of the 34 women had exact knowledge about birth control and how to achieve it. Among them was one who had made use of a pessary on the advice of a doctor and one whose husband had made systematic use of a condom. Some of the women had heard or read about preventive measures but had not known to whom to turn for advice.

The outstanding lesson to be learned from this study is that women who wish to terminate their pregnancies do so not for a single reason, but for a combination of reasons. Women in these circumstances are not so much in need of a special department dealing with abortions, or another department dealing only with sex problems, as of a department for advice on all family problems.

Between November, 1948, and May, 1949, 83 women were admitted to a gynecological hospital in Uppsala for legal induction of abortion. After a detailed discussion with a doctor, as many as 30 of these 83 voluntarily decided to dispense with this measure. None of the 30 subsequently regretted this decision. In line with this experience is that of Dr. Gösta Carlsson, who has concluded psychic follow-up examination of 200 women for whom legal abortion had been induced in 1949 in the county of Stockholm. As many as 60% admitted to a sense of anxiety and remorse a year after the abortion, and only 25% said they did not regret the abortion.

One of the chief objects of the abortion law was to prevent the illegal induction of abortion. Strange as it may seem, this law has apparently had the opposite effect. In coming to this conclusion, Dr. Axel Ingelman-Sunberg, of the Sabbatsberg Gynecological Hospital, has made a careful statistical study of the effects of the abortion law in the Stockholm area in the period 1940-1949. Up to 1947, the number of legal abortions rose and the number of illegal abortions fell, but since then the number of illegal as well as legal abortions had risen markedly, presumably because the abortion law has made the community abortion-minded, and women who have experienced or heard of the cross-examinations preceding the legal induction of abortion often prefer an illegal abortion undertaken by persons who dispense with awkward questions.

The Swedish Medical Association is urging the minister of health to issue up-to-date, quarterly statistics concerning the legal induction of abortion. These cases numbered about 500 a year during the first few years after the abortion law of 1938 was put into effect: in 1949 this number had jumped to 5,503. In 1950 there were some 6,400 applications for the induction of abortion, and permission was given in about 5,900 cases. Altogether, in the 10-year period 1939-1948, consent was given to as many as 15,920 legal abortions. The mortality in 1948 for legal abortions was 0.8 per thousand. The population of Sweden is now approximately seven million.

DENMARK

ACTH in Skin Diseases.—At the dermatologic department of the Rigshospital in Copenhagen, 12 patients suffering from various skin diseases have been given injections of a Danish pituitary adrenocorticotropic hormone (ACTH) preparation. Giving an account of their experiences with these cases in the organ of the Danish Medical Association, *Ugeskrift for Laeger*, for February 22, Drs. H. Brodthagen, Fl. Reymann and M. Schwartz state that the dosage and duration of the treatment varied considerably, depending on the clinical reaction and, to some extent, on the quantity of the drug available. Their dosage of 20 to 45 mg. in the 24 hours was divided into three injections. It was considerably less than the dosage usually given elsewhere, but it seemed to be sufficient, to judge by the steroid excretion from the urine and the eosinophil-leukocyte count. The diseases treated were lupus erythematosis disseminatus (two cases) pemphigus vulgaris (two cases), psoriasis (four cases), scleroderma diffusa (two cases), periarteritis nodosa (one case), and epidermolysis bullosa (one case).

The results obtained were varied. The reaction in an apparently hopeless case of pemphigus vegetans was dramatic. After only a few days the large excoriations began to heal, and there was no new crop. The treatment was continued for 68 days, and there was no sign of relapse after it had been discontinued for a couple of months. The other pemphigus patient was also rendered symptom-free in a few days. However, when the treatment was discontinued after a month, a relapse occurred on the fourth day. Renewal of the treatment brought prompt cure, but when the treatment was discontinued after a little more than a month, a relapse followed in a few days. ACTH is now to be combined with antibiotics with results to be recorded later. The reaction in the four cases of psoriasis was disappointing. Redness and infiltration began to disappear in one of these cases after the treatment had lasted only two or three days, but when intensive treatment had been given for 19 days and the dosage of ACTH was thereupon halved, there was a speedy return of symptoms. Neither of the two patients with scleroderma benefited greatly from the treatment, though there was some reaction to it. The patient with periarteritis nodosa (diagnosis verified by muscle biopsy) received large doses of ACTH for 22 days but derived no benefit from it.

What Do the Elderly Think and Need?—"De Gamles By" (Old Folks' Town) is the name of an institution in Denmark housing several hundred elderly persons. One section of it is for those who can move around freely. Drs. E. Kjörboe and N. Vinther-Paulsen selected 100 men and 100 women for a special inquiry. All 200 were over the age of 65, and most of them were between 65 and 85 and had lived in the institution for more than three years. They were asked what they thought of having to live with other old people, out of contact with young people. Only 11% replied that they missed daily contact with young people and that they were depressed by the constant sight of debility. This did not necessarily mean that the remaining 89% revelled in the company of their contemporaries, for only 11% of the men and 19% of the women had formed new friendships with their fellows in the institution. The attitude of these old persons to each other was often suspicious, as witness the common remark "It is best to keep oneself to oneself, to listen and not to speak." Most of the 200 lived four to a room (new buildings provide only single bedrooms). Of 82 men who shared a bedroom with others, 25% were unwilling to have a bedroom to themselves and 11% were indifferent on this subject. It was generally agreed that four to one bedroom was too much, whereas two to a bedroom was held to be the ideal by many because it provided company and a sense of security in case of sudden illness.

The institution does not provide for organized occupational therapy, but some two score of its inmates helped in the garden, peeled potatoes and served food in return for a modest weekly wage. Regular work was also undertaken by 36% of the men and 18% of the women. Those who had no work were asked if they missed it. Half the men and only one-fifth of the women admitted that they did so. The men suffered more in this respect, because the women were better able to employ themselves with needlework and knitting. While 56% of the women helped to pass the time with some hobby or other, only 7% of the men did so. Twenty-nine per cent of the men and 21% of the women had no employment of their own and did not miss it. Many (21% of both sexes) complained that time hung heavy on their hands. One of the most important conclusions drawn from this investigation, reported in the organ of the Danish Medical Association, is that in institutions for the aged much greater provision must be made for the occupation of the inmates than has hitherto been the case. It is difficult for the aged on their own initiative to acquire new hobbies and interests, so that it would seem that hobbies should be cultivated earlier in life.

Tuberculosis Studies.—The position Denmark occupies with regard to the tuberculosis death rate is stressed by a pamphlet recently issued by the British National Association for the Prevention of Tuberculosis. On page 1 of this pamphlet a list is presented of 15 different countries and their respective tuberculosis death rates in 1948. The following figures refer to the number of tuberculosis deaths per hundred thousand of the population. Denmark, with 30, is first on the list. The United States, with 33, is next, and Holland with 37, is third. Fourth on the list are England and Wales, with 51; Sweden is next, also with 51. Norway is eighth on the list, with 65, and Scotland is ninth, with 72.

It is in keeping with Denmark's lead in this field that the tuberculosis studies published in recent years bear the mark of painstaking thoroughness. In its number for March 15 of this year, the organ of the Danish Medical Association, *Ugeskrift for Laeger*, publishes a whole series of statistical studies of tuberculosis. One of these studies, by Dr. Knud Winge, emphasizes that, when a wholesale search is made in a community for new cases of tuberculosis by mass radiography, the yield of new cases is much higher in a tuberculous environment than in the community taken as a whole. He shows that, among the 1,265 members of tuberculous households examined in Copenhagen in the period 1946-1948, as high a proportion as 3.2% were found as new cases, whereas this was the case with only 0.24% of all the 327,888 persons examined in the same period. Another study, this one by Dr. G. Falkenfleth, concerns the discovery of new cases of bacillary pulmonary tuberculosis in the county of Randers in the period 1944-1949. Among these 607 new cases, there were as many as 61, roughly 10%, found to be tuberculous in a general hospital to which they had been admitted for some other ailment, such as asthma or dyspepsia.

Inaccuracies in Medical Certificates.—The drafting of medical certificates by doctors in Denmark is regulated by law. Doctors are told to word their medical certificates with care and without prejudice. There is also an unwritten law according to which the authorities delegate the supervision of doctors in this respect to the Danish Medical Association, which is expected to keep good order in its own house. This more or less informal disciplinary function has of late given the Danish Medical Association much trouble. The opening sentence of an editorial notice in the organ of this body, *Ugeskrift for Laeger,* reads: "With growing frequency and from important quarters the Central Committee is receiving complaints concerning medical certificates. These complaints are carefully examined. Sometimes they are entirely unwarranted, but not infrequently they are only too well justified." The same editorial goes on to point out that this state of affairs cannot be tolerated, partly because it is in itself objectionable and destructive of the good repute of the medical profession, partly because tolerance may very easily impair the tacit goodwill the authorities have shown in allowing the profession to administer justice in this matter. The disciplinary powers held by the Danish Medical Association are by no means negligible, and it promises to be much stricter in its exercise thereof than it has been hitherto. It can be so partly by instituting arbitration proceedings, partly by requiring higher penalties for convicted offenders, and partly by publishing their names.

BUREAU OF INVESTIGATION

A WARNING TO DOCTORS AND HOSPITALS

A Case of Narcotic Addiction.—The case of Bernard J. Messing Jr., a meperidine (demerol®) addict, has been brought to the attention of the Bureau by a Pennsylvania physician. He comments that the case illustrates some of the weaknesses in existing narcotic legislation and points the way to needed action.

Bernard J. Messing Jr. is described as a 28 year old, white male, weighing about 140 to 150 pounds, with light brown hair, swarthy or yellow complexion, fine pointed nose, and a tattoo on the right forearm inscribed "Dorthy Moore." He has great difficulty and hesitation in pronouncing the letter 'S' as in Samuel and 'F' as in fox. He does not have pupil constriction, tremor, or visible scars along the vein. Scratches on the skin, which the patient attributes to injuries in his alleged occupation of trucker, are actually the source of blood which he mixes with his urine before exhibiting it to the nurses. Scratches on the back of the left hand may be the means of ready identification.

Recently this man appeared at a Pennsylvania hospital, complaining of pain in the left kidney region and in the left loin, and saying that he had passed a stone some months previously. He was admitted to the hospital after furnishing a urine specimen containing blood, and was given meperidine preparatory to cystoscopy. Negative results of cystoscopy and urinalysis brought an admission from this patient that he had been using meperidine since 1949.

He hitch-hikes from place to place and, apparently, has made his way from hospital to hospital for the sole purpose of obtaining meperidine and, incidentally sustenance. He has gained admittance to hospitals in Florida, Virginia, North Carolina, West Virginia, and Pennsylvania. There is indication, also, that he signed an Admission of Guilt of Blue Grass Charges at the United States Public Health Hospital at Lexington, Ky., in 1950.

Inasmuch as there were no facilities for institutionalizing this man in Pennsylvania, it is reported that arrangements were made to transport him voluntarily to the federal institution in Kentucky. The last heard from him, after he had been placed on a bus for Kentucky, was a postal card from Pittsburgh which indicated that the man did not intend to report.

Presuming that the pattern of claimed attacks of renal calculi will continue, doctors and hospitals in western Pennsylvania, Ohio, Indiana, and northern Illinois should be alerted. The addict apparently does not object to cystoscopy. If he is encountered, local police should be notified, with the request that he be held for federal agents.

MEDICAL MOTION PICTURES

Resistive Exercises in Physical Therapy for Thoracoplasty: 16 mm., color, sound, showing time 25 min. Produced in 1950 by Physical Medicine and Rehabilitation Division, Department of Medicine and Surgery, Veterans Administration. Procurable on loan from Presentation Division, Veterans Administration, Washington 25.

This film describes the steps in the development of resistive exercises for tuberculous patients who have undergone a thoracoplasty. It is pointed out that pronounced skeletal deformities often follow this operation and that resistive exercises improve the therapeutic results. Skeletal deformities are minimized or eliminated by proper exercise. Tables are shown indicating that in the group of patients who were not exercised after thoracoplasty, negative sputum developed in only 55%, whereas in the exercise group negative sputum developed in 71%. Complications were higher in the nonexercise group, and deaths during the first year following operation were also higher in this group. It is mentioned that exercise can be used without fear of harmful effects.

A team of workers including the surgeon, the ward physician, the physiatrist, and the physical therapist carry out the treatment program. The physiatrist and the physical therapist orient the patient prior to operation, and treatment is started a week prior to operation. Excellent diagrams of the operation and of the subsequent deformities are shown, and demonstrations on a skeleton indicate the various deformities. Detailed demonstrations of exercises during the recumbent stage, which lasts four to eight weeks, exercises during the semi-weightbearing stage, and exercises during the weightbearing stage are given. It is concluded that months of careful training and the guidance of a team are required before the patient is finally well enough to go home to a useful life.

The photography and narration are excellent, the demonstrations are clear, and the entire program is outlined in superb fashion. This film is recommended to thoracic surgeons, physiatrists, tuberculosis specialists, physical therapists, and all workers who are concerned with the rehabilitation of tuberculous patients.

Welton: 16 mm., color, sound, showing time 29 min. Produced in 1950 by Campus Studios, University of Washington. Procurable on rental or purchase ($190.00) from Instructional Materials Center, 401 Administration Bldg., University of Washington, Seattle 5.

Welton is a story of a town with troubles that have been the result of a failure to use modern methods of administration for the health protection of the community. General unsanitary conditions, disease outbreaks, poor water, inadequate sewage disposal, and poor community housekeeping have made the position of a county commissioner untenable. In seeking a way out, he discusses the problems with the health officer of a neighboring community in which a modern health department is being operated with all the protections commonly used by professionally qualified public health personnel in county health departments. The body of the film is an illustrated discussion of the workings of this health department as they are observed by the uninformed county commissioner from Welton. The reaction to what he sees and hears leads to the establishment of a community council, which ultimately develops a health department and a health center.

The film is designed primarily for the promotion of local councils and health departments and is intended for adult use in order to interest citizens in supporting public health activities in their community. The film could be used in schools of public health, medical schools, nursing schools, and other college units concerned with teaching public health and preventive medicine, particularly at the professional level as an illustration of a fairly well-organized health department. It would also be useful at the junior and senior high school level in social science and possibly biologic science classes. The picture is well cast, and the actor's portrayals are characteristic of the various shades of community interest and responsibility which they represent. The photography and narration are very good.

MEDICAL LITERATURE ABSTRACTS

Pigmented Purpuric Lichenoid Dermatitis: Its Possible Pathogenesis and Report of Case. F. C. Combes and J. Groopman.—p 483

Penicillin and Artificial Fever in Neurosyphilis.—The authors treated 81 patients with neurosyphilis with a combination of fever and penicillin. Most patients were given procaine penicillin in oil containing 2% aluminum monostearate. The usual dosage was 300,000 units injected intramuscularly daily except Sundays for 20 injections. Some of the patients received a total of 9,000,000 to 10,000,000 units. Artificial fever was administered by means of the "blanket method," four or five episodes of fever with temperatures of 104 to 105 F. for five hours being given during the period of penicillin administration. The cell count, protein content and colloidal gold reaction of the spinal fluid tended to revert to normal within one year after institution of treatment. Using the Dattner-Thomas formula as a measure of activity, the authors found that 94.8% of the patients whose spinal fluid was positive before treatment showed a normal or less positive fluid after therapy. The clinical response in patients in whom the disease was symptomatic before treatment had a tendency to parallel the changes in the spinal fluid. The clinical response was satisfactory in most patients, although patients with tabes dorsalis did not benefit greatly. Severe cases of primary optic atrophy were resistant to the treatment. Four patients with mild or moderate degrees of primary optic atrophy improved satisfactorily. While penicillin therapy alone is of great value in the treatment of neurosyphilis, a combination of penicillin with fever therapy is indicated for patients with the tabetic form of dementia paralytica, for those with primary optic atrophy and for those who do not respond satisfactorily to penicillin alone.

Aureomycin in Early Syphilis.—In November 1949, the authors reported on the aureomycin treatment of 27 persons with dark-field positive syphilis. Aureomycin caused an initial satisfactory decline in the serologic titer, rid the lesions of surface spirochetes in an average of 39 hours and, when administered orally in high doses, caused a mild to moderate degree of gastrointestinal disturbance in nearly all patients. These authors now report on the treatment of 67 patients with dark-field positive syphilis, including those in the preliminary report. Sixty-two of the patients had secondary syphilis, two seropositive and three seronegative primary syphilis. An initial oral priming dose of 2 gm. was given, and this was repeated four hours later; then 1 gm. was given every four hours, day and night, until a total of 70 gm. of aureomycin had been administered in 11⅓ days. Sustained high blood levels of aureomycin were easily maintained by the oral route. Aureomycin was detectable in the cerebrospinal fluid in 50% of the patients during the multiple oral dose schedule. Preliminary results indicate that aureomycin is effective in the treatment of early syphilis; continued studies are necessary for determination of its effectiveness after longer periods. The results of aureomycin therapy were compared with those obtained in patients who were treated by the intramuscular administration of 2,800,000 or 3,400,000 units of penicillin. There were no significant differences in seronegativity rates, satisfactory results or failure rates; that is, the effect of aureomycin approaches that of penicillin.

Prognosis in Arterial Hypertension.—Griep and his associates present an eight to 10 year follow-up study of 117 hypertensive patients under 53 years of age with blood pressures initially exceeding 160/110. Forty-six per cent of the 117 had died from hypertensive complications, 2% from unknown causes, 6% for reasons unrelated to high blood pressure and 46% were still alive at the end of the 10 year interval. The type of hypertensive death was almost equally divided between cardiac and cerebrovascular causes. The most important factor in the prognosis was the initial presence of vascular disease, as manifested by cardiac enlargement, electrocardiographic changes, albuminuria or hypertensive encephalopathy. The effect of such complications on mortality rate was independent of the height of the blood pressure, sex distribution or other known variables. Factors of lesser individual prognostic value were (1) height of the diastolic blood pressure, (2) sex of the patient (mortality rate in males was higher by a ratio of 3 to 2) and (3) degree of hypertensive retinopathy. The age of the patient, estimated duration of hypertension and frequency and severity of headaches

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

or dizziness at the time of the initial examination did not appear to play a significant role in increasing the mortality rate. Only four cases of grade 4 fundi, so-called malignant hypertension, in association with a normal nonprotein nitrogen were included in this study. These all had the usual fatal prognosis. Blood pressure showed little tendency to change in the survivors or in those who died of hypertension. The authors emphasize the fact that the height or change in blood pressure level as a prognostic sign in hypertension is unreliable. It is important to determine the degree and progression of vascular damage in the heart, brain, kidneys and retina before mortality rates in any series of hypertensive patients can be evaluated, and this information is vital in the choice of treatment for patients with essential hypertension.

Terramycin.—The antibacterial action of terramycin was studied in 108 cases of infection, which included 28 cases of urinary tract infection, 38 cases of bacterial pneumonia, 21 cases of pertussis, 6 cases of tonsillitis, 4 cases of bacillary dysentery and 11 miscellaneous infections, including one case of amebiasis, one of typhoid and one of subacute bacterial endocarditis. Each adult patient received 1 gm. of terramycin orally every six hours; children received doses of similar magnitude according to weight. Ten adult patients with pneumonia received 250 mg. of terramycin intravenously twice daily. Toxic reactions were rare, and in only one instance were they severe enough to require discontinuation of the drug. In patients who received 1 gm. of terramycin orally, significant amounts remained in the serum after 24 hours. There was no cumulative effect with the prolonged administration of 1 gm. daily or at intervals of six hours. Clinical improvement was noted in 24 of 28 patients (85%) with urinary tract infection, and there was at least temporarily sterile urine in 20 (71%). Resistant strains of Escherichia coli were isolated from five patients before therapy. Urine cultures were sterile after terramycin treatment in two of these patients; there was pronounced clinical improvement in one, and there was no improvement in two. Drug resistance developed in two patients during treatment. One patient with Pseudomonas aeruginosa infection had a sensitive organism in vitro and responded well to therapy. Eighteen of 21 children (86%) with pertussis responded to terramycin with clinical improvement. Five of these had associated bronchopneumonia which cleared in four. The results indicated that the terramycin is as effective in the therapy of pertussis as chloramphenicol or aureomycin. Favorable results were observed in 22 of 25 cases of pneumonia in children and in all of 13 adults with bacterial pneumonia. Favorable responses were noted in patients with bacillary dysentery, tonsillitis, erysipelas and bronchiectasis. The patient with typhoid responded favorably to terramycin therapy, both during the initial attack and during relapse. In one patient with subacute bacterial endocarditis and another with amebiasis, definite clinical improvement was noted, although it was necessary to change to other chemotherapeutic agents in both instances. Two patients with mumps complicated by orchitis and one with infectious mononucleosis immediately improved when terramycin was administered.

Combined Penicillin and Streptomycin in Enterococcic Endocarditis.—Seven patients, four men and three women, with enterococcic endocarditis were treated with combined penicillin and streptomycin. The organisms isolated from these patients all possessed the biologic characteristics of the enterococci and all gave a positive reaction with Lancefield group D antiserum. The patients received 500,000 units of crystalline penicillin intramuscularly every two hours and 0.5 gm. of streptomycin or dihydrostreptomycin intramuscularly four times daily. Two of the seven patients received combined therapy for only brief periods before death and are not considered as having had adequate trials of therapy. The remaining five were given the combined treatment for 28 to 42 days. Results were striking, with quick, permanent arrest of the infection in four. Blood cultures became negative within 48 hours after the start of therapy in all instances and remained negative. The fifth patient had a questionable relapse and subsequently died, but there was no evidence of uncontrolled infection. These results are superior to those achieved with penicillin alone. It is believed that this is the treatment of choice for enterococcic endocarditis and bacteremia. Clinical results suggest that there is a synergistic effect of the two antimicrobial drugs in vivo. In vitro experiments demonstrate a complete algebraic summation of the effects of the two drugs on the enterococci. A suggested mechanism for the summative action is the elimination by streptomycin of members of the bacterial population partially inhibited but not killed by penicillin. The combined use of antimicrobial agents appears to offer an effective method of achieving permanent arrest of some infections that are suppressed only temporarily by a single drug.

Effect of Antibiotics on Streptococcic Tonsillitis.—The relative efficacy of penicillin and aureomycin in the treatment of 475 patients with streptococcic exudative tonsillitis or pharyngitis was evaluated by clinical, bacteriologic and serologic methods. Intramuscular injections of procaine penicillin G in peanut oil with 2% aluminum monostearate were given to 197 patients. The dosage was 300,000 units on admission, 300,000 units at 48 hours and 600,000 units at 96 hours. Eighty patients received 1 gm. of aureomycin immediately, then 0.5 gm. every four hours for 24 hours and 0.25 gm. every four hours for the next three days. The total dose was 8.5 gm. in four days. There were 198 patients serving as controls and receiving no treatment. Results showed that aureomycin was somewhat more effective than penicillin in lowering the fever and causing rapid subsidence of symptoms. Neither drug exerted an appreciably beneficial effect on the abnormal physical signs. They were equally effective in inhibiting antibody formation. Penicillin usually eradicated the carrier state, whereas aureomycin failed to influence the incidence of convalescent carriers. Earaches seldom developed in patients treated with these drugs. With either drug early treatment is required if the disease process is to be materially shortened.

Lipid Pneumonia.—A survey of 389 chronically ill patients revealed 57 cases (14.6%) of lipid pneumonia diagnosed by microscopic examination of the sputum, aspiration from the lung and roentgenologic studies of the chest. Most of the patients used mineral oil as a laxative. Others had used nose drops of various oil-containing medications. The sputum of 55 patients showed lipophages or abundant amounts of free lipid material characteristic of lipid pneumonia. Aspiration from the lung also revealed typical lipid-containing macrophages. Twenty patients showed characteristic roentgenographic manifestations of lipid pneumonia. Thirteen revealed retrocardiac changes consistent with oil aspiration pneumonia in lateral, oblique and, when indicated, overexposed film studies, although the posteroanterior films did not show such lesions. A significant number of the patients had a productive cough and positive physical signs, most frequently observed over the base of the right lower lobe. Examination of the sputum and, when necessary, of material aspirated from the lung are valuable procedures for making the diagnosis of lipid pneumonia. The fact that the disease progresses after discontinuance of the incitant oily factors is possibly due to reaspiration of disintegrated lipophages.

Treatment of Thyroid Tumors with Radioactive Iodine.—Experience with the treatment of 30 patients with nodular goiter associated with hyperthyroidism showed that the goiters regressed in size and the associated hyperthyroidism was controlled better when multiple small doses of I^{131} were given at intervals of six to eight weeks than when single larger doses were used. Radioautographs showed that I^{131} is taken up irregularly by nodular goiters; most of a given dose, regardless of its size, may be concentrated in small, actively functioning areas. Large areas not functioning actively may receive little or no radiation from a single dose of I^{131}. After the most active areas are destroyed or inactivated by a small dose of I^{131} it appears that the less active areas can in turn be inactivated or destroyed by subsequent small doses. Experience in nine patients with papillary carcinoma of the thyroid who were given tracer doses of I^{131} before operation showed that papillary carcinomas of the thyroid tend to take up I^{131} in an irregular manner, as does nodular goiter. One patient, aged 31, with papillary carcinoma of the thyroid was given a total of 335 mc. of I^{131} in eight doses in the course of 18 months and an additional 80 mc. of I^{131} making a total of 415 mc. The primary tumor and its cervical metastases disappeared in response to these multiple doses of I^{131}. If the tumor does not take up I^{131}, and if normal thyroid function has been abolished, the resultant increase in thyrotropic hormone may stimulate growth of the tumor. This could be avoided by the administration of desiccated thyroid in doses of 3 grains (0.20 gm.) or more daily.

Self-Healing Epithelioma of the Skin.—Self-healing epithelioma of the skin is a neoplasm that is microscopically identical with well differentiated squamous carcinoma but that shows a tendency to spontaneous healing. A man aged 69 gave a history of recurrent growths on the skin since the age of 23 that healed with much scarring. One of these, an epithelioma on the perineal skin of six months' duration, was removed. Pathological examination showed highly differentiated epithelioma associated with chronic inflammatory change, fibrosis and regressive changes in the invading tumor. Two months later two active lesions were observed on the right forearm and one near the left wrist. Clinically, these were obvious squamous epitheliomas, but one of them showed partial healing, with scar formation. Biopsy of this lesion showed well differentiated, invasive squamous carcinoma and much round cell infiltration. The healed end of the lesion showed fibrosis of the cutis with a rather thin and atrophic epidermis. No attempt was made to excise the lesion, and healing was complete four months later. Contact with the patient was lost, but eventually the author was informed that the patient had died from rapid and extensive recurrence of the anal lesion two and a half years after the operation. Thus the capacity of healing had failed eventually in this patient. Of the patient's five sons, three, aged 21, 29 and 38, were affected in the same way. All three were studied. Lesions had developed on the ears, face, wrists and legs. Capacity for healing was obvious in all three for a certain time, as evidenced by many scars, but was feeble or absent by the time they came under observation. Almost all the lesions appeared on the exposed surface of the body, but there was no obvious physical or occupational cause to account for this, except for the possibility that normal ultraviolet radiation may play some part. Areas treated by roentgen irradiation remained inactive, but further lesions developed on the face. It is probable that surgical measures will be more helpful, although any method of treatment will present difficulties owing to the awkward distribution of the lesions and the possibility of new ones appearing.

Single Ventricle with Rudimentary Outlet Chamber.—The occurrence of a single ventricle with a diminutive outlet chamber is rare. It is thought to represent an early arrest in cardiac development, with failure of formation of the interventricular septum and persistence of the bulbus cordis as a rudimentary outlet chamber. A case is reported in a 17 year old male, who was first seen in March 1948 because of dyspnea and cyanosis, which he had had since the age of 13 weeks. His growth and development were delayed. He did not walk until 2½ years of age. He was small and underweight. His mental development was normal. As he grew older his limitations were more noticeable, so that when he was first seen in the clinic he was able to walk only 100 yards before becoming short of breath and fatigued. The results of physical, laboratory, fluoroscopic, electrocardiographic and angiocardiographic examinations are described. An exact diagnosis could not be made, but, on the assumption that the basic malformation was a complete transposition of the great vessels, an auricular septal defect was created to allow a better exchange of oxygenated blood within the heart. Following the operation, there was definite improvement. The patient was less cyanotic and dyspneic. A right hemothorax developed that required tapping on several occasions, but, by the fifth postoperative day, the patient appeared to be doing well. On the seventh postoperative day, following a thoracentesis, dyspnea developed, the patient went into shock and died within 10 hours. The relation between the anatomic findings on necropsy and the clinical features and the data obtained from cardiac catheterization and angiocardiography are discussed. Death was probably caused by a massive hemothorax.

Oral Penicillin in Lobar Pneumonia.—Fifty patients with pneumococcal lobar pneumonia were treated with penicillin. Thirty-seven received only aluminum penicillin by mouth, and 13 received intramuscular penicillin in addition to or instead of oral penicillin. Those treated by mouth were given 300,000 units every 12 hours until they were afebrile for 72 hours. The response to oral therapy alone was entirely satisfactory. Actually, there was a higher incidence of complications or death in the 13 parenterally treated patients, who received crystalline penicillin G. However, this may be explained by the greater severity of the disease in that group. So that the possible hazard of delayed penicillin absorption by severely sick patients may be avoided, an initial parenteral injection followed by continued oral therapy is recommended.

Gold Dermatitis Treated with BAL.—This paper presents the history of a woman who was given intravenous injections of gold sodium thiosulfate for arthritis. After the third injection she complained of a severe frontal headache and "noises" in her head. Several hours later she noted an eruption on both palms, which shortly spread to involve the rest of her body. She felt very warm and thirsty. On the next day the eruption covered her body and her temperature was 103.4 F. She was hospitalized. Thirty hours after onset of symptoms, treatment was instituted with BAL (2, 3-dimercaptopropanol, British Anti-Lewisite) in a dose of 1.8 cc. of a 10% solution per injection. This was given intramuscularly every four hours for six doses for the first two days. Thereafter, the patient received one injection in the morning and one at night for the remainder of her hospital stay. Five days after admission, the eruption had cleared completely, including even the petechial rash. All the patient's complaints had disappeared; she was ambulant and anxious to be discharged. The toxic, allergic, cumulative effects of gold on the skin, hemopoietic system, nervous and gastrointestinal tracts and renal and hepatic organs are discussed. The probable mechanism of the action of BAL is reviewed. Although it is a powerful antidote for toxic reaction from gold, continuous vigilance is still paramount.

Seminars in Industrial Psychiatry.—This paper describes one way in which the skills of psychiatry are being made available for the solution of practical problems in industry. It is a report of a teaching project being conducted in industrial plants in Cincinnati under the auspices of the department of psychiatry and the institute of industrial health of the University of Cincinnati. The project is designed primarily for the postgraduate fellows in industrial medicine. Since the fall of 1948 conferences have been held weekly in two plants. These conferences are attended by the medical director, the psychiatrist, either the personnel director or plant manager and the industrial medical fellows. The procedure of these conferences is described, and it is suggested that this method of psychiatric consultation and teaching will prove valuable in the promotion of mental hygiene in industry.

Allergy in Sinobronchitis.—It has been widely recognized that in children there is a relationship between sinus disease and chest disease. More recently it has been suggested that sinobronchitis is a complicating factor in childhood asthma. In a previous study

Price and Solow had been concerned with the prevalence of sinobronchitis among 384 children whose symptoms of chronic respiratory infection necessitated roentgen studies of the sinuses and lungs. In a control group of 26 patients with no respiratory symptoms roentgen evidence of sinobronchial disease was present in only two (7.7%), whereas of 331 patients who had chronic respiratory symptoms 37.4% had demonstrable sinobronchitis. From among this latter group were separated the records of 62 patients, who had been studied in the hospital allergy clinic, and in whom the admitting physician had found a family or personal history of acute or chronic allergy manifested specifically as urticaria, asthma, hay fever, eczema, tracheobronchitis or food sensitivity characterized by angioneurotic edema or gastrointestinal disturbance. In summarizing their observations the authors say that 64% of allergic children 5 years of age or under who were hospitalized for chronic respiratory disease had roentgenographic evidence of sinobronchial disease. Sinobronchitis was noted in 57% of the allergic children who had positive skin test reactions. Those who had a familial history of allergy together with positive reactions to skin tests showed susceptibility to lower respiratory tract infection. The laboratory procedure of examining smears of the posterior pharyngeal secretions for eosinophils (indicative of an allergic response) proved 84% accurate among 26 pediatric patients included in this study.

Hypersensitivity to Streptomycin.—This report is concerned with the development of hypersensitivity to streptomycin in 447 patients who were treated with it and with four cases of contact dermatitis in nurses who were handling streptomycin. One of these four began after six weeks of exposure, the others after three months or more. It was found that hypersensitivity is relatively much commoner in persons who handle the drug than in those who ingest it. Hypersensitivity may manifest itself as drug fever, a maculopapular rash, urticaria or exfoliative dermatitis. It usually appears only after prolonged and intimate contact. Before streptomycin therapy is started information on possible contact with the drug should be obtained and, if necessary, patch tests or intradermal tests should be done. The administration of a full therapeutic dose to a person who has become sensitized (usually a nurse or a pharmaceutical worker) may be disastrous and even fatal. Patients who are hypersensitive to streptomycin must be desensitized or they cannot receive the drug. Personnel who have become hypersensitive must either be desensitized or must give up all contact with streptomycin. Two of the aforementioned nurses who had become sensitized could be desensitized, whereas the other two had to avoid further contact with the drug.

Brucella-Agglutinin Blocking Factor in Human Serum.—The occurrence of erythroblastotic disease in Rh-positive infants born of Rh-negative mothers whose serum fails to show the presence of Rh agglutinins has refocused attention on "nonagglutinating," "incomplete" or "blocking" antibodies that prevent agglutination in test serums. In an effort to determine the practical significance and the possible theoretical implications of the Brucella agglutinin-blocking phenomenon, Schuhardt and associates tested 521 human serums for agglutinins for Brucella abortus and 498 of these for Brucella agglutinin blocking. Four hundred and eighty of the serums were negative for both agglutinins and blocking activity. The remaining 18 showed Brucella agglutinin blocking at titers of 1:40 to 1:320. The blocking effect was completely eliminated when the serums were heated at 56 C. for 30 minutes in all but three serums and was reduced in these three. In nine serums the destruction of the blocking effect resulted in the unmasking of Brucella agglutinins at titers of 1:40 to 1:80. The developing test proved that the Brucella agglutinin blocking is due to an antigenic component of human serum, probably a nonagglutinating antibody.

ACTH and Cortisone in Panhypopituitarism with Arthritis.—Schrock and associates observed the effect of administration of pituitary adrenocorticotropic hormone (ACTH) and cortisone on the moderately active rheumatoid arthritis of a patient with panhypopituitarism. The patient was a woman, aged 46. The authors hoped to obtain information concerning: 1. What direct action, if any, pituitary adrenocorticotropic hormone might have on the clinical and laboratory observations of rheumatoid arthritis, inasmuch as adrenal cortical function was apparently absent. 2. Whether return of adrenal cortical activity would become apparent after pituitary adrenocorticotropic hormone administration. 3. The response to cortisone. Partial adrenal cortical activity was demonstrated during pituitary adrenocorticotropic hormone administration. The effect on the arthritis was equivocal after administration of pituitary adrenocorticotropic hormone but was definite after administration of cortisone. Clinical, chemical and hematological data are in agreement with present concepts of the metabolic and therapeutic properties of pituitary adrenocorticotropic hormone and cortisone. There was clinical and laboratory evidence that some bit of adrenal cortex remained and was responsive to stimulation by pituitary adrenocorticotropic hormone. This response, mediated through the adrenal glands, was shorter and less intense than the general response to substituted cortisone.

Adrenocorticotropic Hormone in the Nephrotic Syndrome.—In children with the nephrotic syndrome several agents, including pituitary adrenocorticotropic hormone (ACTH), may produce diuresis similar to that sometimes occurring spontaneously. This paper reports a study of the mechanism of diuresis produced by pituitary or adrenocortical hormones. An attempt was made to disclose consistent changes that might precede diuresis and, to this end, relevant physiological measurements were made, including blood volume, discrete kidney functions, concentrations of electrolytes and nitrogenous constituents of serum, metabolic balances of electrolytes and nitrogen, serum lipid fractions, and urinary protein and sediment. Observations were made on eight children with the nephrotic syndrome. It was found that the diuresis occurring during or following administration of pituitary adrenocorticotropic hormone was usually associated with improvement in kidney function. Repeated diuresis in children with initially reduced function may be associated with progressive increases in rates of glomerular filtration to normal values. These observations demonstrate a potentiality for improvement in function beyond that commonly considered possible in the nephrotic syndrome of many months' duration. It is believed that these changes are not peculiar to diuresis associated with pituitary adrenocorticotropic hormone administration but may accompany spontaneous or other types of induced diuresis. The studies suggest that increases in plasma volume and glomerular filtration rate are associated with the mechanism of diuresis in children with the nephrotic syndrome.

Differential Diagnosis of Gastric Lesions.—Cytological examination of gastric contents was performed in 54 patients. A set period was permitted to elapse between the collecting and fixing of the specimen. The Papanicolaou stain was then employed. The diagnosis of carcinoma of the stomach was definitely established by laparotomy or autopsy in 11 and on clinical and roentgenologic grounds in four. Carcinoma was excluded in the remaining 39 patients, in 22 by laparotomy or autopsy and in 17 on clinical and roentgenologic grounds. Of the 15 patients with proved carcinoma, smears were positive in eight (53.3%). One smear was doubtful, while six were false negative. Of the 39 patients without cancer of the stomach, 34 (87.2%) had negative smears. The smears of four were doubtful, while one had false positive smears. The Papanicolaou procedure appears to be chiefly of value as corroborative evidence for clinical and roentgenologic observations. The presence of tumor cells in a smear is of significance, and exhaustive study should be done to exclude cancer of the stomach. The relative high incidence of false negative smears indicates definitely that cancer should not be ruled out solely on the absence of tumor cells in a smear.

Fatal Pancytopenia Following Antihistamine Administration.—The occurrence of pancytopenia with death after the use of antihistamine drugs in a man aged 65 with chronic eczema is reported. The patient used between 3 and 4 oz. (90 and 120 gm.) of tripelennamine (pyribenzamine®) hydrochloride cream, and he also occasionally used pyranisamine (neo-antergan®) in doses of 25 mg. three times daily. Three months later, a diagnosis of thrombophlebitis of the left femoral vein was made and the patient was hospitalized for bishydroxycoumarin (dicumarol®) therapy. Routine blood cell counts were made, showing a red cell count of 2,940,000 and a white cell count of 1,500. Within 11 days, the thrombophlebitis became entirely inactive but the blood cell count had not risen, despite repeated blood transfusions. Finally petechial hemorrhages appeared; the patient's white cell count fell to 300, and he died. Necropsy revealed that the spaces in the bone marrow normally occupied by hematopoietic tissues were largely replaced by fat with numerous red blood cells and only a scattering of nucleated cells, consisting chiefly of lymphocytes and a few plasma cells and macrophages. The lymph nodes were relatively atrophic, with some fat replacement in which the sinusoids stood out quite clearly. These observations were characteristic of aplastic anemia. It is felt that the prolonged antihistamine medication must be considered as a possible etiological factor. This is believed to be the first such case report, although at least five nonfatal cases of agranulocytosis have been reported previously. It is felt that the antihistamines should be used only under the careful supervision of a physician and that routine blood cell counts should be done.

Khellin in Angina Pectoris.—Khellin, a pure crystalline derivative of the eastern Mediterranean plant Ammi visnaga, has been reported to have a powerful and prolonged coronary vasodilator effect in animals. Previous clinical studies indicate that it is of value in the treatment of angina pectoris. In this study, for evaluation of therapy in angina pectoris with khellin, patients with well established angina pectoris were selected from the cardiac clinic of the Boston City Hospital. Carefully controlled observations were made on 26 men and six women, ranging in age from 49 to 81 years. Of the 32 patients, 26 had a decrease in frequency and severity of anginal pains, a drop in glyceryl trinitrate requirements and an increase in exercise tolerance. This improvement was considered pronounced in 11 patients, moderate in 11 and slight in four; the remaining six showed no improvement. The average therapeutic dose was 160 mg. daily; no serious toxic reactions were encountered. The high proportion of favorable results, together with the striking degree of improvement frequently observed, led to the conclusion that khellin, properly used, is a safe and effective drug for the treatment of angina pectoris.

Cortisone in Rheumatoid Arthritis.—Thirty-six patients with rheumatoid arthritis, 21 women and 15 men, were treated with cortisone. Twenty-six patients had severe, seven had moderately severe and three had mild rheumatoid arthritis. Patients were usually started on 150 to 200 mg. of cortisone for the first day or two, after which the dose was reduced to 100 mg. daily and continued for two to three weeks for most patients and then gradually tapered off. The drug was administered by intramuscular route or by mouth. Total doses of cortisone ranged from 0.8 to 9.98 gm., with most patients receiving 2 to 3 gm. The period of administration varied from one week to over five months. Twenty-two patients obtained dramatic relief from stiffness and soreness, followed rapidly by decrease in pain and increased strength and use of the involved joints. Reduction in tenderness of joints and swelling was evident within one week. The remaining 14 patients obtained a lesser degree of relief. Twenty patients were followed up for one month or more after cessation of cortisone therapy, and 17 had a prompt return of their symptoms when cortisone was discontinued. Despite the relatively low dosage schedule of cortisone, in nine patients some signs of hypercortisonism developed. None of these changes were serious. Eight patients had disturbances with an uncertain relationship to cortisone that were classified as complications; one of these patients had a perforated duodenal ulcer without history of previous gastrointestinal difficulty. Encouraging results were observed in six patients who were given the soluble gold salt preparation aurothioglucose in addition to cortisone. The pronounced reduction in the active rheumatoid process due to cortisone allows for more intensive physical therapeutic measures. By preventing the risk of precipitating a rheumatoid flare-up, cortisone may be of significant aid in the rehabilitation of the crippled arthritic patient through various orthopedic reconstructive procedures.

Neomycin in Abdominal Surgery.—Neomycin, obtained from Streptomyces fradiae, differs from its closely related antibiotic streptomycin in that it does not favor the development of resistant forms. Occasionally, however, the growth of Aerobacter aerogenes is not inhibited by neomycin. For this reason in the preoperative sterilization of the bowel phthalylsulfathiazole is given as a supplementary agent, because A. aerogenes has not been observed to develop resistant variants in the presence of this drug. In the absence of obstruction or other contraindications, the following schedule for preoperative preparation has been adopted: low residue diet, castor oil 30 to 60 cc. and, after the first liquid stool, 1.0 gm. of neomycin sulfate is administered together with 1.5 gm. of phthalylsulfathiazole orally on a four hour schedule. The stools are cultured at the end of each 24 hour period. This treatment is continued for three days, but some recent observations indicate that this time might be decreased substantially. Neomycin has been administered orally to approximately 100 patients in the course of one year. Neomycin destroys the bacteria in the gastrointestinal tract very rapidly. Should it be necessary to operate on a person without having had the opportunity of a three day preoperative preparation, it would be possible to evacuate the bowel of its gas and liquid feces and inject a solution of neomycin. When it has been possible to prepare the patient for three days, the bowel is characteristically empty. Resection and anastomosis of the large bowel can be carried out with safety. The combined neomycin-phthalylsulfathiazole method has been used in connection with various types of bowel resection for carcinoma, colitis or polyposis, for operations on the bladder, for resection and enclosure of fecal fistulas, for excision of fistulas in ano and for hemorrhoidectomy. An occasional toxic reaction from the combined administration of neomycin and phthalylsulfathiazole is possible, but reactions due to orally administered neomycin alone will be rare. Evidence suggests that neomycin-phthalylsulfathiazole represents a close approach to the ideal for intestinal antisepsis.

Aberrant Pancreas of Stomach.—The five cases of aberrant pancreas of the stomach presented in this paper were observed by Benner in the course of three years. Two of the five cases were discovered during surgical operations; the other three were incidental discoveries at necropsy. The lesions took the form of a pseudodiverticulum of the gastric mucosa, in the depths of which well differentiated pancreatic tissue and ductlike structures were encountered. A common feature was a moundlike elevation of the mucosa. A continuous circle or lip of mucosa outlined an opening ranging from 1 to 5 mm. in diameter. The opening led into a pouch or pocketlike space. These pseudodiverticula varied in depth from 0.5 to 1 cm. and seemed to extend to about the level of the boundary between mucosa and submucosa. In the submucosal connective tissue beneath these pouches the pancreatic tissue was found. The described pseudodiverticulum of the gastric mucosa was never found without associated pancreatic tissue. The gross morphology may prove of great value in identification of aberrant pancreas in the stomach, which is frequently misinterpreted as a malignancy and leads to unnecessarily radical surgery. Although aberrant pancreas frequently persists throughout life without symptoms it may produce pyloric or intestinal obstruction, and all the diseases that affect the pancreas proper may occur in aberrant pancreatic tissue.

Antabuse Therapy in the Army.—The 50 patients selected for treatment with tetraethylthiuram disulfide (antabuse) included both active duty personnel and veterans addicted to alcohol. Detoxification and "drying out" with modified insulin and an abundance of nourishing food prepared the debilitated alcoholic patient for treatment with antabuse. This is important because this drug may cause violent reactions. Abstinence from alcohol was required for at least seven days before tetraethylthiuram disulfide was given for four days in the following schedules: first day, 2 gm.; second day, 1.5 gm.; third day, 1 gm., and fourth day, 0.5 gm. On the fifth day, breakfast was withheld and the blood pressure, pulse, respiration, and temperature were recorded and the patient was then given 30 cc. of 100 proof whisky. Within five to 10 minutes, the patient complained of a disagreeable flushing of the face, which later extended to the neck and upper part of the trunk. The pulse rate sometimes rose to 140. After about 30 minutes both systolic and diastolic pressures begin to fall, the diastolic sometimes dropping to 40 or less. The flushing was replaced by pallor and mild cyanosis. The patient complained of dyspnea, sensations of constriction in the throat, tightness and discomfort in the chest, and nausea. Profuse vomiting and often severe retching terminates the "conditioning situation." Following recovery from the first drinking trial, the patients were maintained on a dosage of 0.5 gm. of tetraethylthiuram disulfide daily for a week. On the eighth day, they were returned to the conditioning room for their second and final drinking trial. After that the patient was given a one week supply of tetraethylthiuram disulfide with instructions to continue on a maintenance dose of 0.5 gm. nightly. He was to return to the hospital at weekly intervals for a new supply of the drug. During the drinking trials, blood samples revealed an abrupt increase in acetaldehyde. The acetaldehyde syndrome sometimes assumed alarming proportions, often with a drop in blood pressure to the vanishing point. Oxygen was routinely administered as soon as it was believed that the patient had been suitably impressed by his experience. It is likely that the lower oxygen tension in the mile-high location of Denver explains both the alarming reactions and the effectiveness of the low maintenance dose.

ACTH in Skin Diseases.—So far most of the skin diseases treated with pituitary adrenocorticotropic hormone have been those that are otherwise intractable and even fatal, that is, pemphigus vulgaris, dermatomyositis and scleroderma. The results have been described as encouraging, or even revolutionary, although there have been very few trials. The results of such treatment at a Copenhagen hospital are reported. One patient with pemphigus vegetans was almost moribund when treatment with pituitary adrenocorticotropic hormone was started, but a dramatic remission occurred, and no relapse had occurred three months after treatment was stopped. Another patient with pemphigus vulgaris relapsed a few days after the discontinuation of the pituitary adrenocorticotropic hormone treatment. Of four patients with psoriasis, only one showed temporary improvement, but all except one showed signs of increased adrenocortical function. Of two patients with diffuse scleroderma one showed moderate improvement while the other remained unchanged. One patient with periarteritis nodosa remained unaffected, despite prolonged treatment. The doses of pituitary adrenocorticotropic hormone and the duration of the treatment varied greatly. The doses, which ranged from 20 to 45 mg. per 24 hours, given in three injections, were substantially smaller than those usually administered elsewhere, but they were completely adequate, since the increase in urinary excretion of steroids was as expected. Undesirable side effects were few, probably because of the small doses given.

Adrenocorticotropic Hormone in Sjögren's Syndrome.—The case is reported of a 51 year old woman who complained of dry mouth and gradual decrease in saliva and tears and of fatigue. She had bilateral keratoconjunctivitis sicca with white filaments, and there were small defects of the corneal epithelium. She also had bilateral swelling of the parotid glands. Considerations of various aspects of Sjögren's syndrome suggested that a trial with adrenocorticotropic hormone might be justified. On the first day of treatment with this hormone she received two injections of 25 mg., then 5 mg. six times daily for the next five days; after this, the dosage was increased to 5 mg. 8 times daily. Twelve days later the dosage was gradually diminished. The treatment was continued for 31 days. The swelling of the lacrimal and salivary glands disappeared, the secretion of saliva and tears reappeared, and the raised temperature and general malaise subsided during treatment. The improvement was maintained for nearly one month after cessation of treatment, but ultimately the patient relapsed. Treatment was accompanied by hypertension and retention of extracellular fluid, a tendency to hypochloremic, hypopotassemic alkalosis, a strongly negative nitrogen balance, increased uric acid excretion, hyperglycemia, and a high excretion of 17-ketosteroids. Spasm of the central retinal artery occurred and resulted in loss of vision in the right eye. Whether this was caused by the adrenocorticotropic hormone or by other factors was not established.

Brain Injury and Menstruation.—The menstrual histories of 78 women aged from 19 to 40 who had had brain injury were studied; menstrual disturbances were found in a large proportion of such women. The changes, which may appear in the next or later menstrual periods and may last months or even years, were usually greater when unconsciousness had followed the trauma. It is assumed that lesions in the pituitary or hypothalamus cause these changes.

Amithiozone in Pulmonary Tuberculosis.—Two hundred and forty patients with pulmonary tuberculosis were treated with 4-acetylaminobenzaldehydethiosemicarbazone (conteben, TB 1-698). For various reasons therapeutic evaluation was possible only in 94 patients. The disease was influenced favorably by the drug in 72 patients. Twenty-one patients were therapeutic failures. An unfavorable course of the disease after gradual temporary improvement was observed in only one patient, in whom amithiozone apparently had activated the process. In a large number of patients who showed improvement leading to clinical and bacteriologic recovery, the drug was combined with other therapeutic measures. This, however, was always under circumstances in which the other measures alone would not have led to recovery. Definite proof of the therapeutic effect of amithiozone was obtained in patients with exudative, mixed exudative-productive, and with predominantly productive processes. Considerable regression of even large cavities, which were refractory to general treatment, was definitely demonstrated in 56 of 87 patients with cavities. Amithiozone was ineffective in patients with old, cicatrized processes. A specific effect of amithiozone on the bacilli and on the pulmonary tuberculous process respectively is considered by the authors. In addition, an indirect effect of the drug on extrapulmonary tuberculous foci may be assumed occasionally. A certain correlation was observed between the size of the administered dose of the drug and the resulting therapeutic effect. The dosage must be individualized, and in each case the maximum well-tolerated dose should be considered the optimum dose. Treatment of adults should be instituted with small doses of 25 to 50 mg. per day, should be gradually increased, and should not exceed 0.3 gm. per day. In general, the dose must be increased to about 0.15 to 0.2 gm. per day for achieving a curative effect. Untoward reactions, mainly gastrointestinal disturbances, may set an upward limit to the dosage. They require constant control, but, provided that this is carried out carefully and with particular attention to signs of liver damage, the untoward reactions do not involve any risk.

Pull-Out Wire Sutures.—The difficulty in obtaining reliable fixation of tendons and ligaments to the skeletal parts, in the exacting anatomic conditions found in the hand, has often been a severe handicap to reconstructive surgery. Bunnell's "pull-out wire technique" undoubtedly makes a suture in such circumstances much easier. Moberg used this pull-out wire technique in tenodeses, attachment of digital ligaments, attachment of ruptured dorsal aponeurosis to the base of the middle or distal phalanx, attachment of flexor profundus tendon to its fractured insertion, in free tendon transplants, in tendon transfers, and for suture of flexor tendons "at a distance." In most of the 101 cases the suture was completely satisfactory. The wire was pulled out after three to five weeks. In no case was the postoperative course disturbed by infection or was there any subsequent loosening of the fixation of tendons or ligaments. The less satisfactory cases were two in which the thread for pulling out the wire broke when it was pulled. This can be avoided, as Bunnell suggests, either if traction is applied to it with a rubber band or if one waits another week before pulling it out. Not the least advantage of the technique has been its simplification of the sutures of collateral and volar ligaments of the thumb and fingers and also of fixation of the torn bony insertion of the flexor profundus tendon. When the tendon has been fixed to the distal phalanx, the suture wire is tied to the free border of the nail after a hole has been made in it. No deformity of the nail persists after the nail has completely grown out.

Infectious Mononucleosis.—Infectious mononucleosis appeared in epidemic proportions at a hospital in Kiel during the spring of 1950. However, in many cases a correct diagnosis was established only on the basis of the differential blood picture. This was the case in 15 of 63 patients who had been hospitalized with a diagnosis of diphtheria or suspected diphtheria. Since only patients who were suspected of diphtheria were hospitalized, it is likely that numerous other patients with infectious mononucleosis were treated elsewhere under different diagnoses, especially since the symptomatology of the disease varies widely. Three different forms are usually differentiated: (1) Pfeiffer's glandular fever, with generalized swelling of lymph nodes (usually occurring in young children); (2) the anginal form (monocytic angina), and (3) the purely febrile form, in which general symptoms predominate. In 13 of the 15 patients reported on here, anginal symptoms predominated, the other two (both children of 18 months) had the symptoms characteristic of Pfeiffer's glandular fever. The importance of the heterophilic antibody reaction of Paul-Bunnel is explained. A positive reaction corroborated the diagnosis in 11 of the 15 cases here reported. In seven instances punctates of lymph nodes or tonsils were examined for further clarification of the diagnosis. This measure, which has been recommended by Lämmler, yielded satisfactory results in only three of the cases, and so the author feels that this diagnostic aid can be dispensed with.

Choline Therapy in Virus Hepatitis.—In cases of virus hepatitis the disorder is supposedly located primarily in the reticuloendothelial apparatus and spreads from there to involve the entire liver. A second type of hepatic lesion results from closure of the bile passages and a third type is exemplified by primary degenerative parenchymal disorders. Choline therapy has been used so far chiefly in this last type of hepatic lesion. The 37 patients reported on here were selected by exclusion of all cases with a toxic etiology; there were signs of impairment of the reticuloendothelial system (monocytosis) but no complicating secondary disorders in addition to the liver disease. Normalization of the bilirubin content of the serum was taken as the criterion of the success of treatment. Ten of the 37 patients served as controls in that they were treated without remedies used in the other groups. The 13 patients of group 1 were treated only with choline; another group of eight patients were given in addition dextrose into the duodenum, and two patients received methionine in addition to the choline. Capsules containing choline chloride were used in the choline therapy. One group of four patients was treated with injections of a choline compound. It was found that treatment with choline reduced the duration of virus hepatitis to about half. Theories to explain the mode of action of choline are briefly discussed.

Dark Adaptation.—Niedermeier mentions the value of liver preparations, vitamin A and vitamin B_2 in the treatment of deficient dark adaptation (night blindness). The blooms of dandelions, having been known as a popular remedy for night blindness, have now been found to contain a substance known as helenin, which is a dipalmitic acid ester of lutein. However, to be effective in the production of visual purple, helenin requires the presence of a certain amount of vitamin A. Therapeutic trials with a daily dose of 0.5 cc. of a 1% oily solution (peanut oil) of helenien (adaptinol) convinced the author that it is effective not only in improving the dark adaptation in cases of night blindness without pathological eye changes but also in the night blindness that accompanies retinitis pigmentosa. Disturbances in intestinal resorption seem to account for failures of this treatment. The author hopes to improve the therapeutic effect of helenien still more by the simultaneous administration of vitamins A and B_2.

Lesions of Bladder and Kidney in Dyestuff Workers.—This report on lesions of the bladder and kidney occurring in workers employed in the manufacture of dyestuffs is based on a review of the literature and on the author's own observations on a total of 161 cases including 43 cases of papilloma, 96 of carcinoma, and 22 of hemorrhagic cystitis. The following substances are probably responsible for the bladder and renal lesions: aromatic amines, aniline, benzidine, alpha naphthylamine and beta naphthylamine, and, in one case, anthracene. These substances are inhaled in the form of gas or dust and are excreted in the urine. Necropsy studies on 55 patients convinced the author that these tumors are highly malignant and produce metastases. The tumors are located most frequently in the region of the trigonum but may occur also in the renal pelvis and kidneys and as polyps of the ureter. Multiple primary tumors that were not the result of propagation or metastasis were observed by the author in 10 patients following occupational exposure to dyestuffs. Coagulation is the treatment in benign cases; in carcinoma, resection of the bladder is necessary, and, recently, total cystectomy has been employed. Preventive measures include changing of certain manufacturing methods so that exposure to noxious substances will be reduced and cystoscopic examinations of workers at regular intervals.

Generalized Staphylococcic Infections.—Three periods of the treatment of generalized staphylococcic infections of the puerperium are reviewed. During the prepenicillin period 1937 to 1943 inclusive, 23 patients with generalized infection due to Staphylococcus pyogenes were treated. Of these, 18 followed abortion and five followed full-term delivery. In this series Staph. pyogenes exhibited an invasive power far exceeding that of other organisms in puerperal infection. Treatment with sulfonamides and staphylococcic antitoxin had little effect on the disease. Of the 23 cases, 10 proved fatal, a rate of 43.4%. Chronic invalidism associated with infective foci on heart valves, in lung, and in joints was common. Between December, 1943, and April, 1946, eight patients were treated with small doses of penicillin (i. e., about 15,000 units every three or four hours); two cases proved fatal. Of the six patients who recovered, only two showed good response to this dosage of penicillin. A small dosage of penicillin, although it sterilized the blood stream, did not necessarily arrest the disease. Early cessation of penicillin therapy favored relapse. At the beginning of the third period patients were treated with 500,000 units of penicillin every three hours. The results indicated that massive doses of penicillin should always be used in proved or suspected cases of staphylococcic septicemia so that there will be adequate penetration of the penicillin into the pyemic abscesses and so that penicillin-resistant strains will not develop. Where there is evidence of endocarditis, penicillin therapy should be continued for at least four weeks. If penicillin therapy does not produce clinical benefit within 48 hours, recourse should be had to aureomycin.

Resistant Strains of Staphylococci.—A total of 603 strains of Staphylococcus pyogenes obtained from 513 inpatients and 90 outpatients were examined for sensitivity to penicillin and streptomycin. Penicillin-resistant organisms were found in 53.4% of the inpatients and 24.6% of the outpatients. For streptomycin resistance the figures were 14 and 1.1%, respectively. Strains resistant to both penicillin and streptomycin were obtained from 72 (14%) of 513 inpatients compared with one of 90 outpatients. This incidence of 14% was significantly higher than the 3.5% obtained with 196 patients examined in the preceding six months. When it became apparent that streptomycin-resistant strains increased in the same way as penicillin-resistant strains, it was of interest to investigate what phage types were involved. It was found that at least 65 of doubly resistant strains belonged to phage types of the genetically related group labeled 6/7/47.

Death After Transfusion with Rh Incompatible Blood. J. Saugman-Jensen and I. Christensen.—p. 1994.

Peritendinitis Calcarea.—Peritendinitis calcarea may appear in acute, chronic, or latent form. In the acute form, the pain is often intense and the motility of the joint limited; local edema is frequent. In most cases there is some elevation of temperature, and the sedimentation reaction is often increased. Clinical diagnosis is verified by roentgenologic demonstration of calcium deposits in the soft parts near the joints, but diagnosis can usually be made without roentgen examination, except sometimes in chronic cases. The latent form is manifested only as an accidental finding. An important characteristic of the calcium deposits in peritendinitis calcarea is the absence of bony structure. Such deposits must be differentiated from sesamoid bones in wrist or instep, myositis ossificans near the upper edge of the acetabulum, which eventually shows bony structure, small bits of bone following trauma, and posttraumatic calcium deposits. The etiology and the mechanism on which the symptoms depend are unknown. The acute form tends toward spontaneous recovery; roentgen treatment shortens the course. In the chronic form the symptoms usually disappear after a series of six roentgen treatments.

Temperature and Sedimentation Reaction in Gastric Ulcer.—Mathisen studied 285 cases of roentgenologically verified gastric and duodenal ulcer. He found an increased erythrocyte sedimentation rate and/or increased temperature in about half the 138 cases of gastric ulcer and in about two-thirds of the 147 cases of duodenal ulcer. In 91 cases there was no plausible explanation for the increased values. Increased sedimentation rates, especially values over 50 mm., were more frequent in gastric than in duodenal ulcer. Assuming that gastric hemorrhage, grave anemia, and blood transfusions may have caused a rise in temperature and increased sedimentation rate, some unexplained cases still remain. The author is inclined to consider an accompanying infection as the cause. Penetrating ulcers may lead to lymphadenitis, lymphangitis, possibly inflammation in adjacent organs, or localized peritonitis, conditions which may be expressed both in sedimentation rate and temperature curve. Cancer of the stomach can occur with or without increased sedimentation rate. This rate may possibly be useful in distinguishing between ulcers that heal spontaneously and those that heal with difficulty, tend to recur, and/or later lead to perforation.

*Gonococcic Vulvovaginitis in Young Girls. J. Carrera.—p. 820.
*Comparative Examination of Neuropsychic Disturbances Observed in Children of Tuberculous, Syphilitic, Malarial or Alcoholic Parents. M. Schachter.—p. 823.

Gonococcic Vulvovaginitis in Young Girls.—Carrera reports that 75% of the cases of vulvovaginitis are of gonococcic origin. The incidence of the disease in the newborn is not high because of maternal hormonal protection; it occurs much more frequently later in childhood. The disease tends toward spontaneous cure and always disappears before puberty. The author points out the ineffectiveness of treatment with irrigations, ointments, washings, and fever therapy. Although estrogen therapy produces temporary relief the dangers that accompany its use, i. e., congestion of the mammary glands, development of secondary sex characteristics, colic, and possible cancerigenic action prohibit its extensive use. Sulfonamide therapy effected a 55% cure rate; combined sulfonamide and estrogen therapy was more effective. Penicillin was more effective than sulfonamides, without the toxic effects of the latter. Streptomycin administered up to a total dose of 5 gm. furnished the best results, since it acts on all the bacilli involved, including gonococci and streptococci. The author concludes that streptomycin is always indicated in the treatment of vulvovaginitis in young girls whether gonococci enter into its etiology or not.

Neuropsychic Disturbances of Children of Tuberculous, Syphilitic, Malarial, or Alcoholic Parents.—Schachter investigated the neuropsychic disturbances that occurred in children whose parents (either one or both) suffered from tuberculosis, syphilis, malaria, or alcoholism. All cases were eliminated in which there was more than one known cause of disease. One hundred and ten children of tuberculous parents, 109 of syphilitic parents, 116 of malarial parents, and 166 of alcoholic parents were observed. The two main types of neuropsychic disturbances that were observed in these children were psychopathic and neuro-organic. The highest percentage of psychopathic disturbances was found in children of alcoholic parents. The results further showed that parental alcoholism and syphilis play an important role respectively in the predisposition toward epilepsy. Syphilis of the parents alone seemed to be dominant in the group of children with encephalitis. Parental alcoholism and tuberculosis were found to have an important effect on the physical and sexual development of the children in this study. Finally, children of alcoholics and of syphilitics showed the greatest percentage of cases of mental and sexual retardation.

*Note on 40 Cases of Typhoid or Paratyphoid in Children Treated and Cured with Chloromycetin. J. Marie, P. Seringe, G. See and P. Marland.—p. 630.

Chloramphenicol in Treatment of Typhoid or Paratyphoid.—Forty nursing infants and children with typhoid or paratyphoid were treated with chloramphenicol (chloromycetin®). Nursing infants and small children were given orally 0.05 to 0.10 gm. of the drug per kilogram of body weight. Older children received a total dose of 1.5 to 2 gm. daily. Treatment with these doses administered in tablets was continued for eight to 15 days. Untoward reactions reported by others, such as collapse or severe digestive disturbances resulting in death, were not observed by the authors. They caution against a massive initial dose of the drug and advise administration of half the dose for the first two days of treatment. With this technique, fever may be prolonged (from two to five days), but typhoid deaths, which were already few in children before antibiotic therapy was instituted, may be eliminated. In the authors' patients rapid defervescence occurred within seven days and frequently within four days. Recovery without sequelae resulted in two patients with severe typhoid encephalitis. Nearly complete recovery from typhoid osteomyelitis of the metacarpus and phalanges occurred in one instance. Only two of the 40 patients had recurrences. Serum diagnosis was made on a strongly positive Widal reaction in all instances, which appeared after the usual interval.

*Study on Degree of in Vitro Sensitivity of Gram-Negative Bacilli and Particularly of Enterobacteriaceae to Several Antibiotics (Penicillin, Streptomycin, Dihydrostreptomycin, Chloromycetin, Aureomycin, Terramycin, Neomycin). A. Lutz, A. Witz, A. Troussel and others.—p. 1.
Considerations on Our Cases of Fetal Death in Utero. J. P. Blum and G. Korsec.—p. 15.

In Vitro Sensitivity of Gram-Negative Bacilli to Antibiotics.—The in vitro sensitivity of strains of Salmonella, Escherichia coli, Paracolobactrum, Proteus, Alcaligenes faecalis, Pseudomonas aeruginosa, and Shigella to six antibiotics (penicillin, streptomycin, dihydrostreptomycin, chloramphenicol [chloromycetin®], aureomycin, and terramycin) was studied. The action of neomycin on several strains of Escherichia coli and Proteus also was studied. Results were as follows: Titrated Salmonellae were highly sensitive to chloramphenicol, terramycin, and aureomycin. No resistant strain was observed. The strains of E. coli and Paracolobactrum that were sensitive to streptomycin, as well as those that were resistant to it, were highly sensitive to chloramphenicol, aureomycin, and terramycin. The strains resistant to streptomycin were sensitive to neomycin but had more pronounced individual differences in their sensitivity to this antibiotic than to terramycin. Nearly all the strains of Proteus mirabilis, P. vulgaris, P. rettgeri and P. morganii were sensitive to chloramphenicol. Only two resistant strains were observed, and only one of these two was highly sensitive to neomycin. Only terramycin was highly active against Pseudomonas aeruginosa. This study like all others of this type suggests caution in the use of antibiotics even though they may have been chosen carefully, because other pathogenic agents, which in a latent state may have been associated with the agents that were inhibited by the antibiotics, may take their place.

Ugeskrift for Laeger, Copenhagen

113:137-166 (Feb. 1) 1951

*Conservative or Combined Conservative-Operative Treatment of Acute Hemorrhage from Ulcer. J. Pedersen.—p. 137.
*Surgical Treatment of Bleeding Gastric and Duodenal Ulcer. K. H. Køster.—p. 144.

Conservative or Combined Conservative-Operative Treatment of Acute Hemorrhage from Ulcer.—Pedersen's analysis of conservatively treated cases of acute ulcer hemorrhage shows that the mortality rate is increased in patients with perforation, pronounced pain during hospitalization, hemorrhage after admission, pyloric stenosis, and cachexia. The mortality rate is not increased in those who have had earlier operation for ulcer or earlier manifest bleeding. He proposes the following lines of guidance for surgical treatment of acute bleeding ulcers, the preliminary requirements being that the diagnosis of chronic ulcer can be made or is probable, that blood transfusion was given directly after admission, and that there are not definite contraindications to operation. In the 60 to 70 year age group operation should be performed immediately after the first hematemesis in the hospital. Operation is absolutely indicated if the hematemesis produces hemorrhagic shock or if the patient has pyloric stenosis or pronounced pain during hospitalization, and operation is recommended when the diagnosis of chronic ulcer is regarded as certain. In the 40 to 50 year age group operation should be done after the first hematemesis in the hospital only if several of the absolute conditions are fulfilled. In the age group under 40 operation is to be considered only in exceptional cases and then only after full conservative treatment has been tried for a longer time. Routine operation for patients aged 70 or over is not advised as too little is known of the operative mortality rate in this group; if operation is to be attempted in suitable cases it should be carried out immediately after the first hematemesis in the hospital.

Surgical Treatment of Bleeding Gastric and Duodenal Ulcer.—Køster says Pedersen has shown that almost all fatal cases of bleeding gastric ulcer occur in a small group of patients aged 40 or over, who have hematemesis after hospitalization. Of 32 patients in this category admitted to Bispebjerg hospital and Blegdams hospital during the past two years, seven remained in medical divisions and 25 were transferred to the surgical department. Three of these were discharged without operative treatment; two died without operation, and in 20 stomach resection was done. One patient operated on, a woman aged 62 with ulcer 6 by 8 cm. and heart block, died two weeks after operation. From his study the author concludes that the selection of patients for operative treatment as proposed by Pedersen makes rational application of the best principles for treatment of bleeding gastric ulcer, namely, avoidance of operation in all those not in danger (patients under 40 and patients with melena) and operation on those who are in danger (patients over 40 with hematemesis after admission) without waiting for massive hemorrhage.

BOOK REVIEWS

Recovery from Aphasia. By Joseph M. Wepman, Ph.D., Clinical Instructor in Otolaryngology (Speech Pathology) and Lecturer in Psychology, *University of Chicago*, Chicago. With foreword by Wendell Johnson, *Director of* Speech Clinic, State University of Iowa, Iowa City. Cloth. $4.50. Pp. 276. The Ronald Press Company, 15 E. 26th St., New York 10, 1951.

With heightening interest in all phases of rehabilitation, this book appears at a propitious time to serve as a guide for those concerned with the care of the aphasic patient.

Covering the essential historical data and giving his classification of aphasia, which has the appeal of simplicity, Dr. Wepman lists the essential members of the rehabilitation team. He includes, as he should, the nurse at the bedside, the many physicians involved, the aphasia therapists, and the family. He sees the team functioning at its best in the hospital situation, but tries to present the idea that an individual "aphasia therapist," trained in the technique of speech, education, and psychology, might be able to function in practice.

The author recognizes with skill and clarity that the patient whose brain is damaged by trauma or disease presents a many-faceted problem, because the resulting language disorder distorts and frequently prevents adequate social communication. The interrelation of language and personality, and the impossibility of treatment of one to the exclusion of the other, is likewise brought out. The emphasis is on the necessity for consideration of both if there is to be hope for recovery. The patient with brain injury suffers from a "disorder affecting (his) total reaction pattern due to a disturbance of the integrating capacity of the cortex." With this in mind, the author proceeds to outline a therapeutic program which is based on a varied, flexible approach to the "whole" man and which recognizes that the aphasic adult is, as a result of his cortical upheaval, a different man, with a changed capacity, a modified integrative ability, and a new concept of self. The author gives specific approaches and direct therapeutic techniques for the receptive, expressive, and mixed aphasias. The book is recommended as a textbook for workers in speech pathology and therapy, and clinical psychologists, and should be extremely valuable for neurologists, psychiatrists, otolaryngologists, and other physicians who must deal with the aphasic adult. Dr. Wepman writes succinctly and effectively. He is well qualified with much experience as a therapist and teacher with soldiers with brain injury. The format and bibliography are excellent.

Malignant Disease of the Female Genital Tract. By Stanley Way, M.R. C.O.G., Gynaecologist to Newcastle Regional Cancer Organization, Newcastle-on-Tyne. Cloth. $5. Pp. 279, with 38 illustrations. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1951.

The aim of the author was to prepare a book not only for those practicing gynecology, but also for radiotherapists and perhaps even pathologists, because it contains information concerning diseases which they encounter but which lie outside the spheres of radiotherapy and pathology, yet are of great importance if their special knowledge is to be integrated into the subject as a whole. The book deals with carcinoma of the vulva, vagina, cervix, body of the uterus, ovary, and fallopian tube; sarcoma of the genital tract; miscellaneous malignant tumors, and pregnancy complicated by malignant tumors.

This book is based on Way's experience, which has been extensive. For example, the author has studied 314 cases of vulval carcinoma, 64 cases of cancer of the vagina, 1,368 cases of carcinoma of the cervix, 79 cases of corpus cancer, and 130 cases of carcinoma of the ovary. The author agrees with most gynecologists that the treatment of carcinoma of the vulva is essentially surgical. He emphasizes that no carcinoma of the female genital tract is more difficult to treat successfully than a carcinoma of the vagina. He sums up the present position in regard to treatment of carcinoma of the cervix by stating that the most suitable case for surgery is the case that does best with radium treatment, but that surgery can cure about ten per cent of cases in which radium at present fails. In the case which responds favorably to radium, irradiation can do more and with a lower mortality than surgery. In the very early cases of corpus carcinoma, adequate irradiation can produce results nearly as good as those achieved by surgery, but if these two conditions are not fulfilled, then the results fall a long way short of adequate surgical treatment. The results of treatment of cancer of the ovary cannot be good, and the operability is depressingly low. The problem is mainly one of early diagnosis.

This book contains all the essential information about malignant tumors of the female genital tract. It is very well written; it is definitely authoritative, and the recommendations made concerning therapy are in accordance with the ideas of the leading authorities in the world. The inclusion of many tables, illustrations, and roentgenograms helps the book considerably. All gynecologists, radiologists, and tumor specialists should surely possess this book.

Watch out for the Weather. By Jacqueline Berke and Vivian Wilson. Cloth. $2.95. Pp. 226, with illustrations by Lombard C. Jones. Viking Press, Inc., 18 E. 48th St., New York 17, 1951.

In spite of the hopeful attitude taken in this book, the accumulated evidence that weather is important, and the apparent proof that it may affect some disease conditions, one has the feeling that the outlines of this thesis are still far too hazy. One encouraging fact stands out, however: man is beginning to do something about the weather besides talk about it. Whether these small beginnings will ever resolve weather problems on a scale that will be significant remains to be seen. Some of the evidence in the book supports this concept. Other points negate it.

In the chapters in the first part of the volume, the authors make a valiant effort to show that weather changes can cause or affect disease, but there is a strong suspicion that the long arm of coincidence is being overlooked. To say, for example, that appendicitis follows the weather would appear to be far fetched. And the opinion of the authors that summer stomach infections are due apparently only to blood "settling" in the outer areas of the body, leaving the intestines undefended, ignores too many other recognized factors.

Nevertheless, the volume makes interesting and instructive reading, especially those chapters dealing with polluted air, modern weather men, man-made weather, and the question of whether our weather is changing. The authors attack vigorously the concept that tuberculous patients find little or no benefit from moving to different climates. One conclusion that will surely stand unchallenged is that the southern portion of this country is a better place to live, although no evidence is presented that disease has left that area completely. For those interested in following up this subject, there is a rather extensive bibliography.

Your Sinus Troubles and Treatments: An Authoritative Explanation for the Layman, with Recommendations for the Treatment of Your Sinus Conditions, Colds, Hay Fever and Other Allergies. By Friedrich S. Brodnitz, M.D. Cloth. $2.50. Pp. 243, with 10 illustrations. Abelard Press, Inc., 381 Fourth Ave., New York 16, 1950.

Like many of his medico-literary colleagues, the author believes that rather than leave medical writing to journalists with second-hand information, physicians should take the lead in satisfying the public interest in matters pertaining to health. To meet the challenge, he has written in simple colloquial language a sane book on sinus disease. Commencing with a description of the nasal cavity and its functions, Brodnitz proceeds to discuss nasal and sinus infections in their various ramifications, touches on such related topics as hay fever and nasal allergy, and concludes with a sound evaluation of contemporary medical and surgical sinus therapy.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Lust-Pfaundler, *Krankheiten des Kindesalters: Ihre Erkennung und Behandlung in der Praxis.* Neubearbeitet von Prof. Dr. Josef Husler, Chefarzt des Kinderkrankenhauses Munchen-Schwabing. Sixth edition. Cloth. 22.80 *marks. Pp.* 683. Urban & Schwarzenberg, Thierschstrasse 11, München 2; Meinekestr, 13, Berlin W. 15, 1950.

This book is not, as the title may suggest, a textbook of pediatrics but a manual for the practicing pediatrician. It is divided into three parts. The first part (445 pages) contains brief diagnostic and more elaborate therapeutic notes on children's diseases. These are listed by chapters according to age groups, causes, and organ systems. The second part (40 pages) deals with diagnostic and therapeutic techniques described in alphabetical sequence. The third part (152 pages) is an alphabetical list of prescriptions and preparations. The practical usefulness of this guidebook to pediatric practitioners should be considerable, and for this reason, it is highly recommended.

One wonders, however, whether the practitioner might not be hampered in the daily use of the manual by its physical bulk and the accumulation of time-honored ballast. He would do better with less of either and with stronger guidance toward the really essential. For example, it should be possible in the second and third parts to eliminate descriptions of such procedures as air baths, hardening, and "connective tissue massage," and of numerous therapeutic specialties and obsolete drugs. Similarly, the table of some 20 artificial infant feedings (page 38) is supplemented in part three by elaborate cooking recipes. Most of them are dispensible in pediatric practice. The essential factor here is clean sterilized cow's milk, which may or may not be diluted or reinforced. For treating infantile diarrhea, the practitioner needs two modifications: boiled skimmed milk and natural or artificial buttermilk. To suggest to him more complicated mixtures only deflects his attention from the supreme lifesaving essential: subcutaneous and especially intravenous administration of sufficient amounts of crystalline solutions (Ringer's, glucose, and lactate). Introduction of solid food in the normal infant's diet is suggested as late as age 5 and 6 months (page 29).

The chapter on "Constitutional and Metabolic Disorders" (page 69) deals with the so-called exudative and lymphatic diatheses, diabetes mellitus, obesity, and leanness. The first subject could be safely taken up in the chapters on skin diseases and hematology, the second in that on endocrine diseases, and the last two in the latter chapter as well as among those on the juvenile neuroses and psychopathic traits (which, by the way, are very neatly discussed).

The original author of this book is the late Dr. F. Lust of Karlsruhe, whose eighth edition, his last, was published in 1934. Displaced from his hospital position under Nazi racial laws, he committed suicide shortly thereafter. It seems fitting to establish the present edition and any later editions of this book as a memorial to Dr. Lust.

A Textbook of the Practice of Medicine. By Various Authors. Edited by Frederick W. Price, F.R.S.Ed., M.D., C.M.Ed., Consulting Physician to Royal Northern Hospital, London. Eighth edition. Cloth. $9. Pp. 2076. Oxford University Press, 114 5th Ave., New York 11; Amen House, Warwick Sq., London, E.C.4, 1950.

The present edition of this excellent textbook of general medicine by 31 British authors, contains many additions and revisions. New articles have been added on antibiotics, sulfonamides, injuries from nuclear fission, cervical intervertebral discs, rehabilitation of paraplegics, South American blastomycosis, filaria, Reiter's disease, chronic intermittent juvenile jaundice, paroxysmal proctalgia, calcified pericardium, diaphragmatic hernia, and other subjects. Numerous articles have been partially or entirely rewritten, and changes in classification and nomenclature have been made. Data on the newer antibiotics such as aureomycin, chloramphenicol (chloromycetin®), terramycin hydrochloride, and viomycin are not included, nor is mention made of cortisone or pituitary adrenocorticotropic hormone. Many recent advances in treatment are included, however. The volume has the advantage over many textbooks of medicine that it has a section devoted entirely to skin diseases. Few of the sections have photographs or diagrams, but the section on clinical electrocardiography is well illustrated. The entire book is well organized and adequately indexed. The emphasis throughout is on the practical details of diagnosis, prognosis, and treatment. This work should prove useful to students and practitioners.

Scoville's The Art of Compounding. By Glenn L. Jenkins, Dean and Professor of Pharmaceutical Chemistry, Purdue University, School of Pharmacy, Lafayette, Indiana, Don E. Francke, Chief Pharmacist, University Hospital, University of Michigan, Ann Arbor, Michigan, Edward A. Brecht, Dean and Professor of Pharmacy, University of North Carolina, School of Pharmacy, Chapel Hill, North Carolina, and Glen J. Sperandio, Assistant Professor of Pharmacy, Purdue University, School of Pharmacy, Lafayette, Indiana. Eighth edition. Cloth. $7.50. Pp. 515, with 77 illustrations. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1951.

This valuable reference book has been made even more valuable by this revision, in which developments of recent years have been included. There is new material in this edition, such as chapters on solutions for special purposes, allergenic solutions, and the inclusion of possible incompatibilities for many of the new medicaments which have carved an indelibile name for themselves in the modern materia medica. All this new information enhances the value of this already widely accepted book on pharmaceutical compounding and dispensing. The chapter on emulsions has been enlarged to include the many new and excellent emulsifying agents and aids. For the student or pharmacist confronted with this book for the first time, it should be made known that the preparations of all types of pharmaceuticals is included, namely, powders, pills, tablets, capsules, emulsions, ointments, and solutions.

Like previous editions, this book is a real aid to the dispensing pharmacist in the accurate compounding of the physician's prescription. In view of the fact that over three-quarters of the book is devoted to new material, it is more valuable than ever in keeping the pharmacist abreast of changes made by the rapid progress of medical research.

The Use of Pedicle Flaps of Skin in Plastic Surgery of the Head and Neck. By Gordon B. New, M.D., F.A.C.S., Professor of Plastic Surgery, and John B. Erich, M.D., F.A.C.S., Associate Professor of Plastic Surgery, both of Graduate School, University of Minnesota, Minneapolis. Publication number 56, American Lecture Series, monograph in American Lectures in Surgery, edited by Michael E. DeBakey, M.D., Professor of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Kentucky. Plastic Surgery Division. Editor: James Barrett Brown, M.D., Professor of Clinical Surgery, School of Medicine, Washington University, St. Louis, Missouri. Cloth. $3. Pp. 104, with 76 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

When a work prepared as a lecture will "stand up to print," there is *ipso facto* evidence of its intrinsic quality. The conciseness and systematic organization of this brief but comprehensive volume is a case in point. The authors have covered their subject well in remarkably small compass.

Controversy is rife, and probably will continue to be, with regard to the technics of choice in plastic surgery. Drs. New and Erich emphasize the fact that they have no intention of setting forth any "unalterable" procedures. Experience at the Mayo Clinic is the basis of their presentation.

The use of pedicle flaps is discussed with particular reference to plastic operations on the head and neck. The various types of flap are described and illustrated. The factors of elevation, delay, and transplantation are given due weight in the discussion. Recommendations for the treatment of both injuries and deformities are clearly set forth.

The illustrations are consistently good. The text is well-written and should be of considerable value to the plastic surgeon.

Diabetes Insipidus. By Harry Blotner, M.D., Associate Visiting Physician, Beth Israel Hospital, Boston, Mass. Edited by Henry A. Christian, A.M., M.D., LL.D. (Reprinted from Oxford Loose-Leaf Medicine with same page numbers as in that work.) Cloth. Pp. 179-194 (188), with illustrations. Oxford University Press, 114 5th Ave., New York 11, 1951.

This monograph, reprinted from the Oxford Loose-Leaf Medicine, presents a comprehensive discussion of the unusual endocrine disease diabetes insipidus. Included are a brief historical résumé, a discussion of the anatomy and physiology of the pituitary gland, a detailed description of the etiology, symptoms, and treatment of diabetes insipidus, and a bibliography of 470 references. Illustrative case reports and laboratory data are included, drawn both from the literature and from the author's personal experience in treating 112 patients with this disease. This book should be of interest to clinicians and to all others interested in endocrine disturbances.

QUERIES AND MINOR NOTES

TREATMENT OF RECURRENT BOILS

To the Editor:—*What is the treatment for preventing recurrent boils in the hair-bearing areas of the skin? The patient is a white man, aged 32. Glucose tolerance tests were normal, and no other abnormal findings objectively or subjectively are present. In the past 15 years the patient has had 30 boils, usually necessitating incision and drainage. A vaccine was made about 12 years ago, with no apparent benefit.*

M.D., New York.

This inquiry was referred to two authorities, whose respective replies follow.—Ed.

Answer.—In patients with recurring furuncles it is advisable to determine the degree of anemia, if any, and the sugar tolerance, as has been done in this case, and to recognize, if present, any other systemic disease. If the patient is anemic, efforts should be made toward overcoming this. The same can be said about the presence of a high blood sugar level, even though diabetes is not demonstrated. The boils should not be incised or drained, as the treatment of the furuncle after it has started is in reality the prevention of a new one. Accordingly, efforts should be made to prevent the dissemination of the bacteria by careful handling of dressings and the use of antiseptic or antibiotic ointments. Local application of moist heat gives relief and hastens the pointing of the furuncle, and the use of penicillin or aureomycin or terramycin will help materially in shortening the course. The use of alcohol sponge baths as a prophylactic measure seems to have merit. Locally, the use of aureomycin ointment, or even ammoniated mercury encircling the boil, with the dressing kept on until the lesion is inactive, is a satisfactory means of preventing spread of the infection. Vaccines have not been very helpful. The prophylactic use of an oral antibiotic, given at the rate of two or three days a week, may be of value in preventing new furuncles.

Answer.—The treatment of chronic recurrent furunculosis is both constitutional and local. Lowered resistance is a contributing factor. Attempts should be made to improve the general health of the patient by means of sufficient rest, adequate sunshine, and vitamins. A diet low in carbohydrates and high in protein should be prescribed. Attempts should be made, if possible, to correct all systemic and visceral disorders, as well as focal infections, such as dead teeth, root abscesses, infected tonsils, prostate, bladder and urinary tract. Autogenous or heterogenous vaccines, as well as nonspecific treatments such as with typhoid vaccine, are valuable in some cases. Parenteral and oral administration of the antibiotics such as penicillin, aureomycin, terramycin and chloramphenicol, sometimes is of value in acute cases. The local therapy depends on the acuteness, chronicity and location of the lesion. In acute cases, wet compresses (boric acid, aluminum acetate solution, bacitracin, terramycin) are helpful. Roentgen therapy is effective in chronic cases, especially those involving the nape of the neck and axillas.

ACTH, CORTISONE AND INFERTILITY

To the Editor:—*I have seen no clear statement on the effect of ACTH and cortisone on the male and female gonads or on sterility. Can you supply this information?*

J. T. McDuffie, M.D., Corning, Calif.

Answer.—A few clinicians are cautiously trying pituitary adrenocorticotropic hormone (ACTH) and cortisone in infertility due to endocrine disorders. Up to the present no significant results have been reported.

OSTEOPOROSIS AND DEMINERALIZATION OF BONE

To the Editor:—*The terms osteoporosis and demineralization seem to be used interchangeably on the x-ray reports that I receive. Are they interchangeable? I have a patient who was given a diagnosis of osteoarthritis and demineralization of bone some years ago, with emphasis on the arthritis, and she was treated accordingly. X-rays were taken by another radiologist; the diagnosis was similar but with the emphasis on the osteoporosis. I would appreciate your suggestions. Also, what would the treatment be?*

George A. Bakke, M.D., Oakland, Calif.

Answer.—The term demineralization of bone covers a much broader field than does osteoporosis; the terms are therefore not interchangeable. Some of the conditions producing demineralization other than osteoporosis are rickets, osteomalacia, hyperparathyroidism, hyperthyroidism, chronic osteoporosis and polyostotic fibrous dysplasia. Osteoporosis is a disease of tissue metabolism and not of calcium metabolism; consequently, it is associated with relatively normal serum calcium and phosphorus levels. Calcium or vitamin D lack per se probably do not cause osteoporosis. There are at least 12 different causes or types of osteoporosis; before outlining treatment one must attempt to differentiate the cause. The most frequently encountered forms are (1) postmenopausal osteoporosis and (2) senile osteoporosis.

The commonest form of osteoporosis is that encountered in women after the menopause, whether it be artificial or normal. There is experimental evidence that postmenopausal osteoporosis is due to estrogen deficiency. A moderate degree of osteoporosis of the spine is almost physiological after the menopause, and the osteoporosis per se probably does not produce pain. Pain usually results from secondary collapse of the vertebrae or marked ballooning of the intervertebral disks together with an invagination of the vertebral plates. Most elderly persons also have osteoarthritis of the spine, which may produce pain. Usually the pain of osteoarthritis is not as severe as that accompanying acute collapse or compression of an osteoporotic vertebra. The patient with painful osteoporosis should be fitted with a Taylor brace or corset with rigid stays and shoulder straps, for the prevention of further pathological fractures of the spine and maintenance of good posture and height. At the same time prolonged immobilization should be avoided, if possible, because of the danger of superimposed atrophy of disuse. The patient should sleep on a firm, straight, nonsagging mattress. Estrogens in the form of estradiol or the synthetic preparation, diethylstilbestrol, might be administered. Albright noted the effect on calcium metabolism of estrogen and androgen in combination was greater than that of either alone in patients with postmenopausal or senile osteoporosis. A suggested combination is as follows: diethylstilbestrol, 0.5-1 mg., together with methyl testosterone, 10-20 mg., daily. It is usually advisable to discontinue the testosterone after two months and sometimes before, if a masculinizing effect becomes evident. The endocrine therapy may have to be modified if it causes edema, since many of the steroids cause sodium retention. Likewise because of the possible danger of cancer it is wise to interrupt the estrogen medication for one week out of every month. The physician should examine the patient at frequent intervals and forever be alert for signs of uterine or mammary carcinoma. Since osteoporosis is due to a deficiency in bone matrix, a high protein diet is indicated; since it is not a disease of calcium and phosphorus metabolism, excessively high intakes of these minerals and of vitamin D are not indicated, although the diet should be adequate in these substances.

Senile osteoporosis is really due to atrophy of the skeleton. It is possible that underfunction of the endocrine glands is responsible in a large measure for the atrophy of old age. The treatment of senile osteoporosis is essentially the same as that of postmenopausal osteoporosis. If testosterone is used in old men, the prostate should be watched and estrogen therapy should

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

be given at the same time, since it has been shown that estrogen neutralizes the stimulating action of testosterone on the prostate.

For further information on demineralization of bone and osteoporosis, the work by Albright and Reifenstein is recommended (The Parathyroid Glands and Metabolic Bone Disease, Baltimore, Williams & Wilkins Company, 1948).

DEMINERALIZATION OF CARPAL BONES

To the Editor:—*A 47 year old housewife has had pain in both wrists for a year and a half, aggravated by work. Past history is negative except for anemia of 13 years' duration requiring occasional liver injections. General physical examination is negative. The right wrist is palpably warmer and more swollen than the left. X-rays of both wrists show demineralization of the carpal bones, more on the right than on the left. Hemoglobin is 12.8 Gm., white blood cell count 8,200, sedimentation rate, Westergren, 8 mm. in one hour. A specialist in rheumatology prescribed contrast baths several times daily. Symptoms have slowly become more distressing, and swelling has increased. The sedimentation rate has remained at 8 over a seven month period. There is slight noninflammatory painless swelling of some of the proximal interphalangeal joints. Can you suggest further diagnostic procedures and therapy?*

Robert B. Engstrom, M.D., Mankato, Minn.

Answer.—The clinical picture in this case is that of rheumatoid arthritis, in view of the symmetrical arthritis of both wrists, with beginning involvement of the proximal phalangeal joints. A normal sedimentation rate is unusual in a process of this duration but by no means rules out this diagnosis. The x-ray findings are also consistent. Constitutional symptoms, especially fatigability, anorexia and weight loss would be helpful diagnostically if present, as would vasomotor instability, numbness and paresthesias. No further diagnostic procedures seem indicated. The patient should profit by general conservative therapy, including acetylsalicylic acid (aspirin) in dosage sufficient to control the symptoms, extra rest periods and a high protein, high vitamin diet. Physical therapy should be prescribed in the form of moist heat and active exercises to preserve motion. Light cock-up splints for the wrists should be worn at night, as well as during the day if there is any tendency toward loss of extension. The process does not seem severe enough to warrant use of cortisone or pituitary adrenocorticotropic hormone (ACTH) on a long-term maintenance basis. Brief courses of either agent will probably confer no lasting benefit. The value of gold therapy in rheumatoid arthritis is still controversial, although a trial of this method might be made under strict supervision if the patient fails to respond to conservative treatment over a period of six months.

PROSTATIC OBSTRUCTION

To the Editor:—*What is the effect of diethylstilbestrol on the noncancerous prostate? Is there a rationale for the use of this substance in 5 mg. doses three times daily for about three weeks and once a day on a maintenance basis for benign prostatic hypertrophy when surgery is contraindicated or refused?* *M.D., Pennsylvania.*

Answer.—Several years ago there appeared a report of a group of cases of urinary obstruction caused by noncancerous prostatic enlargement in which there apparently was symptomatic improvement from the administration of diethylstilbestrol. However, these results were not corroborated by subsequent experience of the majority of urologists. Although in some cases there is apparent symptomatic improvement, this usually is temporary. Prostatic obstruction usually is caused by deformity of the bladder neck resulting from changes in the surrounding prostatic tissue. This deformity cannot be affected materially by slight reduction in the size of the prostate gland and requires mechanical removal to correct it. There is no objection to a trial of diethylstilbestrol in the dosage suggested unless the patient reacts unfavorably to the drug. Surgical removal by transurethral methods or by excision has been found to be the best method of treating prostatic obstruction.

TREATMENT OF UVEITIS

To the Editor:—*Is there any specific treatment for uveitis? What is the most common etiology?* *M.D., Texas.*

Answer.—There are two forms of uveitis, the granulomatous and the nongranulomatous. The first, which has a characteristic clinical picture, may be due to any of the granulomatous diseases, such as syphilis, tuberculosis, brucellosis, sarcoidosis and toxoplasma. The nongranulomatous is the serous or rheumatic form. It is considered to be a manifestation of allergotoxic reaction within an eye sensitized to a specific bacterial product. The responsible organisms are not found in the eye in this last form, in contrast to their physical presence in the uveal tract in granulomatous uveitis. The organisms producing nongranulomatous uveitis are usually various strains of Streptococcus hemolytica and the Gonococcus. Undoubtedly, allergens of other organisms or of other material may be offending agents. The specific treatment of granulomatous uveitis is based on the discovery of the underlying cause, if possible. The various causative agents must be eradicated. In the nongranulomatous form, specific treatment is not available as a rule, except in gonorrhea. Every effort should be made to remove foci of infection. A vaccine made from the organisms obtained from a suspected focus is used to desensitize the patient in the usual fashion. The antibiotics are used with the hope that a hidden focus can be affected.

The use of pituitary adrenocorticotropic hormone (ACTH) and cortisone in uveitis probably suspends the active inflammatory reaction within the eye, during which time specific treatment may be fruitful. These substances are not, however, curatives in themselves. Local application of heat and atropine, watching for secondary glaucoma and instillation or subconjunctival injection of cortisone are suggested for all forms of uveitis. Fever treatment is also of value, regardless of the type present.

TUBERCULIN TESTING

To the Editor:—*What is the consensus regarding the significance of intradermal tuberculin tests in different age groups? Is mass tuberculin testing of school children worth while? If so, in what age groups? Does activation of quiescent lesions occur from repetition of the test?*

T. N. Armistead, M.D., Minden, La.

Answer.—1. Intradermal tuberculin testing, or, better stated, subepidermal testing, as represented by the Mantoux method, is the surest and best method in all age groups. Because it is difficult to get consent from mothers to have "needles stuck into their small children," the Vollmer patch test has been used. This method, when properly applied and read, is equally efficient in children, young adults and most adults with thin, white skin. It generally should be limited to these groups, since many adults with thick and dark skin frequently do not react well or at all.

2. Mass tuberculin testing of school children, once the best and perhaps the only method of survey, has generally been abandoned as a major weapon in case finding, because the cost per case found has been considered too much and, furthermore, the roentgenographic method has generally supplanted it.

The whole problem, however, must be evaluated on the type of material to be surveyed, and a large community of adults is best served by the roentgenographic method. Supplementary tuberculin testing is used in certain cases when there is some doubt regarding the diagnosis, to rule out nontuberculous conditions. In sparsely infected communities, in high schools and even in some elementary schools, the tuberculin test may be used to detect infected foci within the communities. For example, if an infant or a child reacts strongly to tuberculin, it indicates recent association with some open case of tuberculosis. Examination of the families of such children may reveal the source of the infection. Even greater use may accrue from the educational value that such a feature creates in a community. Everybody becomes conscious of tuberculosis, from the child to the parent, which is one of the most desirable objectives of public health programs.

3. The best age group, therefore, is the high school group; there is diminishing usefulness in younger age groups.

4. If a tuberculin test is properly performed, no activation of a previous lesion should result. Of course, a heavy dose of tuberculin must not be used. If enough is given to cause a systemic reaction, a reactivation may occur. In the early days of the use of Koch's old tuberculin, many such reactivations took place. Properly graded dosage from 1:10,000 dilution (0.01 mg.) down to 1:10 dilution (10 mg.), with a 72 hour interval between, will not cause reactivation. The weaker dilution of PPD is also considered to be safe.

DANGER OF INHALING CARBON TETRACHLORIDE

To the Editor:—*Would it be harmful to use carbon tetrachloride to clean a tonometer used in ophthalmology? The method of cleaning would be to saturate a piece of cotton with about 1 cc. of the carbon tetrachloride and cleaning the instrument. This would be repeated 10 to 15 times a day, day after day.* *Edward I. Lipsius, M.D., Philadelphia.*

Answer.—A single milligram of carbon tetrachloride fully evaporated under standard conditions will produce 154 parts per million of vapor in a liter of air. If this figure be extended to the total number of milligrams in 1 cm. and then multiplied by the "10 or 15" applications during the brief hours of the medical office day, it will be readily seen that harmful concentrations of carbon tetrachloride may arise. In the immediate breathing zone of the cleaner of the tonometer the vapor concentration may be enormous. Under the assumption of the worst possible situation, in any assumed office 10×10×10 feet, the concentration in the entire area might reach 130 ppm, which well exceeds the maximum allowable concentration of 50 ppm. In addition, some risk of dermatitis from the defatting action of carbon tetrachloride is involved. Since the bactericidal value of carbon tetrachloride is low, there is little justification for its use for the purpose indicated. For chemical cleaning, alcohol, either ethyl or isopropyl, may suffice even though their bactericidal properties are low. The use of carbon tetrachloride to the end indicated is not commendable and is, in fact, risky. If it be deemed needful to apply some chlorinated hydrocarbon, use trichlorethylene. It is much less toxic and still is essentially nonflammable.

PROCTITIS FOLLOWING USE OF AUREOMYCIN

To the Editor:—*I have had occasion to see about 10 patients who had acute proctitis or procto-colitis from one to three weeks after discontinuing the use of aureomycin or terramycin. I am hoping you will be able to give me data on similar cases if such exist and to outline the best form of treatment.*
C. C. Chewning Jr., M.D., Richmond, Va.

Answer.—Proctitis associated with diarrhea or soft bowel movements, tenesmus, pruritus and perianal dermatitis is commonly observed following aureomycin medication. In fact, mucous membrane irritation has been noted in the pharynx, mouth and vagina as well as the rectum. The reaction may vary from a mild catarrhal condition of the tissues to a severe inflammatory process with superficial ulceration. Because of the frequency of these complications, an increasing number of clinicians are limiting the use of this drug to its absolute indications. Similar but less severe reactions occur with chloramphenicol. Allergic sensitivity or a change in bacterial flora are said to be causative. Antihistamine drugs have been helpful. Manifestations described are less notable when aureomycin is administered intravenously, especially if combined with vitamin B complex. However, this mode of treatment is not without hazard to veins and must be carried out with extreme caution. Practically all will improve spontaneously over a period of three to six weeks. Most patients can be kept comfortable during this period with the usual antidiarrheal and antipruritic drugs. Similar experiences have been published (*Brit. M. J.* 1:1184 May, 1950; *Rhode Island M. J.* 33:137 March, 1950; *Proc. Staff Meet., Mayo Clinic,* 24:612 Dec. 7, 1949; *J. A. M. A.* 142:1137 April 15, 1950, and *J. A. M. A.* 142:198 Jan. 21, 1950).

DURATION OF IMMUNITY TO RABIES

To the Editor:—*Of what duration is the immunity produced by human rabies vaccine, as routinely used in prophylactic treatment, in a case of bite from a rabid animal?*
James M. Fraser, M.D., Grand Lake, Colo.

Answer.—Virus-neutralizing antibody appears in the blood after vaccination with commercial vaccine (phenol or ultraviolet irradiated), reaching a peak at about one month, and holds up well for six months. At one year there is a considerable drop in the amount of virus-neutralizing antibody in the blood, but there is still a good deal of active immunity, as shown by experimental work using dogs as the test animal. The Expert Committee on Rabies of the World Health Organization (Technical Report Series No. 28, Expert Committee on Rabies, November 1950, available from the Internation Documents Service, Columbia University Press, New York City) makes the following recommendation: If reexposure occurs within three months of the first course of vaccine, no treatment is necessary unless the second exposure is of a severe type. If the interval is between three and six months, two reinforcing doses of vaccine given a week apart are indicated, whereas, if more than a six month interval has elapsed, the treatment should be on the same basis as if it were an original exposure. The aforementioned publication gives a concise and comprehensive presentation of rabies prophylaxis.

CONTROL OF DIABETES IN EMPLOYEES

To the Editor:—*We employ a number of diabetics in an industry where minor accidents are frequent and where there are occasional serious traumatic injuries and burns. We do not expect perfect control of our diabetic employees and in the past have required that their nonfasting blood sugar, taken about two hours after a meal, be kept at about 200 mg. per cubic centimeter of whole blood or lower. Several employees have objected to having blood sugar determinations done every two months. The union has now taken up the matter and is quoting authorities. The clinical school of thought apparently does not care how high the blood sugar goes, as long as the patient is taking insulin and shows no clinical symptoms, feels well and is able to work. Faced with the two opposite views, we are at a loss as to how to attempt control. May we have your opinion as to proper check on the control of diabetes?*
H. K. Montgomery, M.D., Dayton, Ohio.

Answer.—The query involves a decision as to whether the control of diabetes pays and, second, what constitutes control. Accumulating evidence shows that those diabetics whose disease is well controlled live longer and have fewer disabling complications. Life insurance companies, before accepting diabetics as risks, give particular consideration as to whether the applicants are under the regular supervision of a physician. That practice might well apply to a firm employing diabetics. A diabetic who does not drink at all is preferred by certain insurance companies. The physician's report about reactions, acidosis and adherence to diet and the wise use of insulin would count much; so, too, would maintenance of weight approaching normal standards; laboratory evidence should be furnished that the urine is sugar free at least once in a day and an abnormally low blood sugar level should be considered just as serious as a high blood sugar level. Physicians' reports and laboratory tests should be rendered every three months. An x-ray of the chest before employment and annually thereafter is desirable and for reference later an x-ray of the lower extremities and an electrocardiogram for those with diabetes of 10 or more years' duration or for those above the age of 40 years.

A reasonable and safe range, without specifying exact figures for blood sugar values, would be 130 to 200 mg. per 100 cc., venous blood, Folin-Wu, before meals. Standards would be stricter if the patients worked with machinery. Permission would be refused to engage in hazardous work involving safety of others. These standards are stated somewhat liberally, but they provide a margin of safety and yet reflect fairly good control of diabetes.

CHRONIC PROSTATITIS AND OLIGOSPERMIA

To the Editor:—*A young man had nongonorreal urethritis four years ago. He was treated with antibiotics, sulfonamides and urethral instillations of silver nitrate. One month later he had symptoms of acute prostatitis. He was apparently cured with massage and dilatation but a few weeks later had a feeling of pressure in the perineum and rectum and nocturnal ejaculations. He was treated and was well for four months; then the same symptoms returned, with prostatorrhea after defecation. The sperm fluid showed oligospermia. He has coitus once every one or two months. What treatment is indicated?*

David Lederman, Bogotá, Colombia, S. A.

Answer.—That chronic prostatitis would explain the various symptoms of the patient or the clinical data noted is open to question. Chronic uncomplicated prostatitis usually does not cause prolonged perineal pain, nocturnal ejaculations or oligospermia. It is assumed that gonococci have been repeatedly excluded by microscopic examination and by culture. The possibility of prostatic calculi should be excluded by means of a roentgenogram including the bladder and prostatic area. Cystoscopic and urethroscopic examination would also be desirable to exclude stricture and the presence of granulations or dilated ducts in the prostatic urethra. Prostatorrhea in itself is not of any great clinical importance, except that it causes the patient to be apprehensive; although it sometimes persists when prostatic infection is largely eliminated, it usually is self limiting and if uncomplicated would require no prolonged treatment.

The significance of oligospermia is dependent on a number of factors. It is taken for granted that there is no permanent constriction of both vasa deferens. It would be advisable to repeat examination of the semen, and the specimen should be collected in a clean, warm flask, the examination being made immediately afterward. The specimen should be obtained at least three weeks after the last act of sexual intercourse. If on repeated examination the sperm count is under 60,000, further examination should be made. The existence of pathological sperms should be noted and the various types enumerated. A testicular biopsy for determination of the nature of the basal cells might also be necessary to guide treatment. There might be a large psychological factor in the patient's attitude toward his symptoms. He should be assured that chronic prostatitis in itself is not a serious complication and will gradually subside if left alone. He should also be assured that oligospermia can be transient and corrected unless other complications are present. It might be well to discontinue local treatment for a while, assuming that his sexual technique precludes the possibility of reinfection.

CATARACTS

To the Editor:—*What is the latest therapy in the early treatment of cataracts?* *M.D., New York.*

Answer.—There is no method of treatment that will reverse the pathological changes that constitute the opacities of the human lens. The loss of transparency of the lens capsule and its fibers and cellular elements is the result of processes initiated by chemical or physical trauma in a broad sense; it is not a disease process per se.

It is generally agreed that cataracts are induced by some constitutional diseases, such as diabetes and parathyroid deficiency, and by inadequate nutrition, as in arteriosclerosis, but a generally satisfactory response to treatment of these diseases does not alter the changes in the lenses once they have appeared. There is no assurance that cataract will or will not develop during the course of such a disease, and there is no basis for prophylactic measures.

Incipient cataract may change in appearance and vary in transparency from time to time so as to influence visual acuity to a small extent over a period of a few months, but such changes are not brought about by any kind of nonsurgical therapy given with the intent of producing certain recognizable and controllable alterations. The latest therapy in the early treatment of cataract is no better than the oldest.

VINYLIDENE CHLORIDE RESINS

To the Editor:—*Have any cases of lumite poisoning been reported over the country? A young woman working at a lumite plant has developed a peculiar type of leukocytosis that does not resemble mononucleosis, granulocytosis or leukemia.* *Hartwell Joiner, M.D., Gainesville, Ga.*

Answer.—Lumite is the trade name for certain woven plastic products derived from one or more vinylidene chloride resins. This type of plastic in finished form long has been regarded as nontoxic. In suspected occupational disease, attention is often focused on the major work material and operation without due regard for ancillary materials and processes. While lumite as such possibly may be disregarded in disease causation, a precise knowledge of the details of work might reveal an offending agent; for example, in the present instance if cotton entered some products and led to cotton dust, the possibility of "mill fever" arises. This disease involves the lungs primarily and calls for roentgen examination. Without any incrimination whatever, it is indicated that better exploration of minor work steps might be productive. For extensive information on vinylidene chloride resins the inquirer should consult the "Modern Plastics Encyclopedia," New York, Plastics Catalogue Corporation, 1947.

FOUL TASTE BEFORE SPELLS OF UNCONSCIOUSNESS

To the Editor:—*A 60 year old man has fallen three times and was unconscious for about 30 minutes each time. He told me that each time just before he fell an odor or taste like rotten eggs came up in his throat. This man used to eat two eggs for breakfast, and each spell has come on a little while after breakfast. He has some gallbladder difficulty, but no other abnormality. Could the eggs have caused a compound to form in his stomach to cause the unconsciousness?*

Perry Parrigin, M.D., Monticello, Ky.

Answer.—Attacks of loss of consciousness immediately preceded by odors or tastes (usually unpleasant) most commonly occur as the result of a tumor in one or the other temporal lobe of the brain. It is far more likely that the patient is suffering from some lesion of the brain, most likely a tumor, than that his attacks are the result of a gastric disturbance. This man should have a thorough neurological examination as soon as possible.

TALCUM IN PERICARDIAL CAVITY FOR CORONARY OCCLUSION

To the Editor:—*Information is requested on an operation for the relief of angina pectoris in which talcum is inserted into the pericardial sac in an attempt to increase the circulation. This has been recently featured in a popular magazine.*

Benjamin Trachtman, M.D., Brooklyn.

Answer.—Dr. Samuel A. Thompson of New York places talcum in the pericardial cavity as a method of treatment for coronary artery disease. Up to the present time he has operated on 45 patients and reports that 85 per cent of the patients show variable degrees of improvement. The operation was based on animal experimentation reported in the *Annals of Internal Medicine* (March 1942, page 495). These experiments showed that talcum in the pericardial cavity had a protective action against ligation of a major coronary artery. Schildt, Stanton and Beck repeated these experiments (*Ann. Surg.* 118:38 [July] 1943); they did not find that talcum had a beneficial effect after coronary artery occlusion. These authors did not apply the operation to patients. In view of this difference of opinion, it would appear desirable that this work be rechecked by another experimental study.

PSEUDOHYPERTROPHIC MUSCULAR DYSTROPHY

To the Editor:—*Is any new information available for treatment of pseudohypertrophic muscular dystrophy?*

William F. Hunting, M.D., Cincinnati.

Answer.—Unfortunately there is no known treatment of any value for this condition.

EFFECT OF PHYSICAL ACTIVITY ON PROGNOSIS OF POLIOMYELITIS

Robert M. Albrecht, M.D.
and
Frances B. Locke, M.S., Albany, N. Y.

Reports of severe paralytic poliomyelitis apparently precipitated by strenuous exertion have appeared in the literature. Russell,[1] in England, studied statistically two series of poliomyelitis cases: one of 44 cases and an additional series of 100 cases.[2] He concluded that exercise during the preparalytic stage greatly increases the danger of paralysis, and that bed rest considerably reduces it. Hargreaves,[3] who studied 30 cases in Cornwall, and Horstmann,[4] who studied 411 cases chiefly from California and North Carolina, have presented data to support his view. However, they could find no evidence that activity before the preparalytic stage influenced paralysis, or that activity at any stage affected the severity of bulbar paralysis.

The present study was undertaken in New York State in July 1949. Its purpose was to determine whether, with certain changes in study technique, the severity of poliomyelitis could be ascribed largely to the extent of physical activity at the time of illness. It was thought that a positive relation would be of major importance because one could then prevent much of the paralysis by keeping patients in bed during the critical period.

MATERIALS

In 1949 there were 381 poliomyelitis cases occurring in patients aged 3 years or more reported from Nassau County. This was a desirable site for study because the Nassau County Health Department has excellent facilities for the follow-up of patients. Also, the diagnoses of poliomyelitis in the cases reported were unusually reliable because doubtful cases were examined by consultation teams, provided jointly by the County Health Department and the County Medical Society. This study is, therefore, a cooperative effort of the Nassau County Health Department and the New York State Department of Health.

Table 1 shows the age and sex distribution of the reported cases in patients aged 3 years or more. Patients under the age of 3 years were not included because of the difficulty of estimating the extent of their activity.

Two hundred and eighty-four patients were investigated in this study. The great majority of those reported but not investigated were cases reported only after the field study was completed in early October. Of the 284 patients investigated, 84 were excluded from the report, most of them because the extent of paralysis was not determined at the prescribed time, others because of vague histories or because the time of onset of the meningeal stage could not be accurately determined. Therefore, this paper reports on 200 cases, whose age, sex and type of paralysis are described in Table 2. The cases presented are a fairly representative sample of the epidemic.

METHOD

In each case a detailed history of the symptoms and of the physical activities from three days before the onset of illness to a number of days after the onset was taken. Seventy-five per cent of the histories were done by one of us (R. M. A.). The remainder, taken by three other investigators, were included in the study because the techniques used by them were comparable to Dr. Albrecht's. Most of the histories were taken within six weeks after the onset of the disease. We found, as Horstmann did, that the events connected with the illness were generally clearly remembered by the patient; the few exceptions were dropped from the study.

From the Bureau of Epidemiology and Communicable Disease Control of the New York State Department of Health; Assistant Director (Dr. Albrecht) and Biostatistician (Mrs. Locke).

This study was under the guidance of Dr. Robert F. Korns, Director of the Bureau of Epidemiology and Communicable Disease Control of the New York State Department of Health. Dr. Anne Bahlke, New York State Department of Health, Dr. Frederic Vosburgh, Nassau County Health Department, and Dr. Warren Winkelstein, Erie County Health Department, assisted in the collection of data. Miss Louise Hayward, New York State Department of Health, gave technical assistance in revising the muscle-grading forms. The cooperation of the physicians and the hospitals, and the work of the physiotherapists, were essential for the completion of this study.

[4] Horstmann, D. R.: Acute Poliomyelitis: Relation of Physical Activity at the Time of Onset to the Course of the Disease, J. A. M. A. 142: 236-241 (Jan. 28) 1950.

The term "paralysis," as used in this report, refers to other than bulbar paralysis, unless otherwise stated. The term "meningeal stage" describes the period of the illness characterized by one or more of the following: a positive Kernig sign, stiffness of the neck or back, and pain in the head, trunk, or thighs. This term corresponds to Russell's preparalytic stage. Several cases were dropped because the onset of the meningeal phase could not be determined accurately.

Physical activities were classed in the histories as follows: bed rest; light activity, such as resting at home; normal activity, such as housework, office work, school or normal play; heavy activity, such as manual labor or strenuous sports or play. (Because there were only five examples of heavy activity in the meningeal stage, they are grouped with "normal activity" in Tables 3*A* and 3 *B*. However, the type of paralysis in these five is described separately later.)

TABLE 1.—*Reported Cases of Poliomyelitis by Age and Sex, Nassau County, New York State, 1949**

	Both Sexes		Males		Females	
Age	No.	%	No.	%	No.	%
3- 4	65	17.1	43	20.1	22	13.2
5- 9	129	33.9	75	35.0	54	32.3
10-19	83	21.7	56	26.2	27	16.2
20 and over	104	27.3	40	18.7	64	38.3
Total	381	100	214	100	167	100

* Excluding patients under 3 yr.

TABLE 2.—*Poliomyelitis Cases in Nassau County Study, 1949, with Age, Sex and Type of Paralysis*

		Type of Paralysis Per Cent Distribution						
Age	Sex	Non-paralytic	Bulbar	Spinal	Deaths	Total	Total No.	% of Total for Sex
3-4	M	22.2	11.1	55.6	11.1	100	9	8.3
	F	8.3	25.0	58.4	8.3	100	12	13.1
5-9	M	42.1	13.2	44.7	0.0	100	38	35.2
	F	44.9	3.4	48.3	3.4	100	29	31.5
10-19	M	29.7	8.1	48.7	13.5	100	37	34.3
	F	40.0	5.0	45.0	10.0	100	20	21.7
20 and over	M	19.2	7.7	38.5	34.6	100	24	22.2
	F	12.9	6.5	64.5	16.1	100	31	33.7
Total	M	31.5	10.2	44.4	13.9	100	108	100
	F	28.3	7.6	54.3	9.8	100	92	100
	Both Sexes	30.0	9.0	49.0	12.0	100	200	.....

The physical activities of the patients were rated by one of us (F. B. L.) who, in order to exclude bias, was deliberately kept uninformed of the extent of their paralysis at the time of rating. In rating the cases, both the type and duration of activity were considered.

MUSCLE GRADINGS

Since the evaluation of the extent of paralysis depends on the skill of the observer, and since the paralysis itself varies with time, an attempt was made to have all of the patients muscle-graded by trained physiotherapists approximately six months after the onset of illness. Actually, all of the cases presented here were graded between five and one-half and seven months after onset. Between the extremes of this period, little change in status can be expected.[5] All except 12 of the gradings were performed by trained physiotherapists from the Nassau County Health Department (the majority), the New York State Rehabilitation Hospital at West Haverstraw or the St. Charles Hospital for Crippled Children at Port Jefferson, N. Y. The 12 exceptions were graded by physicians.

TABLE 3A.—*Degree of Paralysis, by Age and Maximum Activity on Day of Onset of the Meningeal Stage**

	Maximum Activity on Day of Onset								
	Normal			Light			Bed		
Age	S †	M †	L †	S †	M †	L †	S †	M †	L †
3- 9	3	3	14	6	1	13	6	1	31
10-24	9	1	21	2	..	10	8	1	13
25-49	17	3	6	2	..	5	2	1	4
Total	29	7	41	10	1	28	16	3	48

* Excludes bulbar cases.

† S = severe paralysis or death; M = moderate paralysis; L = light or no paralysis.

All of the gradings were tabulated on standard forms for muscle grading used routinely by the New York State Department of Health. These forms are the same as those used by the National Foundation for Infantile Paralysis and list 134 muscles or muscle groups. These 134 were condensed to 82, on the bases of spinal nerve innervation and the ability of the physiotherapist to distinguish accurately the functioning of different muscles, using the method of Bahlke and Perkins.[6] Each muscle or muscle group has a value ranging from zero to five. Zero represents total paralysis; and five normal function. Therefore, a nonparalytic patient is given a score of 410 (5 × 82). Under the heading "severe paralysis" are listed deaths and scores ranging up to 339. "Moderate paralysis" includes ratings from 304 to 389; and "light or none," ratings from 390 to 410.

RESULTS

There was found no correlation between the severity of paralysis and the activity in the three days preceding the onset of illness; nor did activity in the three days before the onset of the meningeal stage seem to influence subsequent paralysis. The bulbar cases were too few to permit conclusions to be drawn.

TABLE 3B.—*Per Cent Light or No Paralysis by Age and Maximum Activity on Day of Onset of the Meningeal Stage**

	Maximum Activity on Day of Onset					
	Heavy-Normal		Light		Bed Rest	
Age	Total No.	% Light or No Paralysis	Total No.	% Light or No Paralysis	Total No.	% Light or No Paralysis
3- 9	20	70.0	20	65.0	38	81.6
10-24	31	67.7	12	83.3	22	59.1
25-49	26	23.1	7	71.4	7	57.1
Total	77	53.2	39	71.8	67	71.6

* Excludes bulbar cases.

Table 3*A* describes for each age group the maximum activity on the day of onset of the meningeal stage and the resulting paralysis.

Table 3*B* shows for each age group the per cent which had light or no paralysis, according to the maximum activity on the day of onset of the meningeal stage. The data for Table 3*B* are taken from Table 3*A*.

---

[5] Lenhard, R. E.: Prognosis in Poliomyelitis, J. Bone & Joint Surg. **32-A:** 71-79 (Jan.) 1950.

[6] Bahlke, A. M., and Perkins, J. E.: The Treatment of Preparalytic Poliomyelitis with Gamma Globulin, J. A. M. A. **129:** 1146-1150 (Dec. 22) 1945.

There is no statistically significant relationship between severity of exercise and severity of paralysis, except in adults.[7]

Data concerning the maximum activity in the first three days of the meningeal stage are not presented. They are practically identical with those shown in Table 3*A*.

Table 4 describes the maximum activity on the day of onset of the meningeal stage of those who died. Ten out of 24 deaths occurred in patients with restricted activity.

Only five patients had heavy exercise on the day of onset of the meningeal phase or thereafter. Their ages ranged from 17 to 41. Of the five, one died, three were severely paralyzed, and one had no paralysis.

Table 5 describes paralysis in individuals according to their handedness. Only 80 patients were studied in this regard. Data on 50 are presented here; 27 others were nonparalytic and 3 died.

TABLE 4.—*Deaths by Age, and Maximum Activity on Day of Onset of the Meningeal Stage**

	Maximum Activity			
Age	Heavy	Normal	Light	Bed
3- 9	..	1	1	1
10-24	..	4	2	3
25-49	1	8	1	2
Total	1	13	4	6

* Including four bulbar deaths: two patients had normal exercise; one, light; and one, bed rest.

TABLE 5.—*Handedness and Site of Paralysis*

Handedness	Left Side More Paralyzed than Right Side	Right Side More Paralyzed than Left Side	Both Sides Equally Paralyzed
Left	0	2	3
Right	7	9	29

Horstmann[4] showed that right-handed individuals tend to have more right-sided paralysis; and left-handed, more left-sided paralysis. No such trend is seen in this table; but the number of patients, especially left-handed, is too small to permit definite conclusion.

COMMENT

Russell[2] stated: "Complete physical rest in bed from the onset of the preparalytic stage greatly reduces the danger of severe paralysis. Severe physical activity at this stage is almost suicidal, while the continuance of even average physical activity is dangerous."

Our data do not support this view. There was no indication in children that a severe outcome was due to activity shortly before the onset of the illness, or at any time during illness. In adults, severe paralysis was more common in those who continued their activity after the onset of the meningeal stage than in those who were in bed during this period. The difference in the adult groups is statistically significant. However, deaths and severe residual paralysis in adults could not be entirely attributed to their activity at this period.

Since adults are more apt than children to continue their routine when ill, it must be determined whether the severity of paralysis of adults is due to their activity or to their age. Our data indicate that age is an important factor and that adults, irrespective of their activity, are more severely affected than children.

Certainly many factors affect the prognosis of poliomyelitis. The previous authors did not claim that severe paralysis was due in all cases to excessive activity, or that bed rest protected at all times from moderate or worse paralysis. They show many cases to the contrary. One factor affecting prognosis is age. Other factors, ill defined, may be the nature of the virus, previous experience with it, the size of the infecting dose and constitutional factors.

It should be noted that our patients were examined five and one-half to seven months after onset; Russell's, in convalescence; Hargreaves', after three months' treatment; Horstmann's, two to three months or more after onset.

Russell and Horstmann did not indicate precisely when their patients were examined. Because the rate of recovery of muscle function is more rapid at first, it is especially important early in convalescence to examine all of the patients at relatively the same time. If this is not done, a difference in the degree of paralysis noted can result merely from a difference in the time of examination.

The epidemic we studied consisted of patients reported by experienced physicians to have poliomyelitis. The age and sex distribution and the proportion of deaths and paralytic cases were those of the usual poliomyelitis epidemic in this state. In this outbreak, the deaths and the cases of severe residual paralysis could not be substantially attributed to the degree of activity of the patient, either shortly before his illness or at any time during it. Parenthetically, the fact that there were only five instances of heavy exertion in the meningeal stage was not reflected in an epidemic of unusual mildness.

SUMMARY AND CONCLUSIONS

1. Two hundred patients from the 1949 poliomyelitis epidemic in Nassau County, New York, were studied concerning their physical activity from three days before to a number of days after the onset of illness, and the degree of residual paralysis five and one-half to seven months after onset.

2. Deaths and severe paralysis in children are not related to the degree of physical activity either shortly before the onset of illness or at any time during the illness.

3. Deaths and severe paralysis in adults may be attributed in part to the degree of physical activity in the meningeal stage.

4. Age is a major factor in the prognosis of poliomyelitis. Adults, irrespective of activity, are more severely affected than children.

5. Factors other than age and activity are of major importance in the prognosis of poliomyelitis.

EFFECT OF TRANSPORTATION ON SEVERITY OF ACUTE POLIOMYELITIS

M. Bernard Brahdy, M.D., Mount Vernon, N. Y.
and
Selig H. Katz, M.D., New York

Often poliomyelitis develops in adults and children in communities where there are no hospitals or where the nearby hospitals are not equipped for their care. Many of these patients are transported long distances to hospitals especially equipped and staffed for the treatment of poliomyelitis. For the past two decades we have had the impression that the disease was severer in patients who were transported long distances. To determine whether this impression was correct, we reviewed the case records of patients admitted to the Willard Parker Hospital during the poliomyelitis epidemic of 1949.

BASES OF ANALYSIS

The diagnosis of poliomyelitis was made on accepted criteria: namely, characteristic changes in the spinal fluid in conjunction with either stiffness of the neck and back muscles or the presence of weakness or paralysis. We determined the community in which each patient became ill with symptoms referable to the central nervous system. This was done by reference to the history given on admission and by interviewing most of the patients old enough to give satisfactory information. These data were checked with the records of the New York City Health Department.[1]

For the purpose of analysis, patients admitted to the Willard Parker Hospital were divided into groups of local patients and transported patients. Most of the local patients came from the borough of Manhattan, in which Willard Parker Hospital is located, and the adjacent borough of the Bronx. Only a few came from Brooklyn or Queens, because these boroughs had facilities for the care of patients with poliomyelitis. Those coming from beyond this area were classified as transported patients. Of course, local patients were also transported to the hospital, but only relatively short distances.

Many New Yorkers leave the city some time during the summer or early autumn and thus become potential candidates for our group of transported patients. For that reason we limited our analysis to this time of the year, when a significant number of both local and transported patients were hospitalized. We included all patients with poliomyelitis admitted to the hospital from June 13 (the date of the first admission of a patient with poliomyelitis in 1949) to Oct. 31, 1949.

We had difficulty in establishing criteria of severity of the disease for the purpose of comparing one patient with another. Does transient paralysis of all extremities indicate a more serious illness than permanent paralysis of one deltoid muscle? Is a paralysis of the facial muscles worse than paralysis of an anterior tibial muscle? To obviate this difficulty we used a definite end point as a criterion of severity; namely, the survival or death of the patient. To determine the immediate effect of transportation, we also noted whether death occurred within 24 hours after admission to the hospital

MATERIAL

During the 20 week period from June 13 to October 31, a total of 493 patients with poliomyelitis were admitted to the hospital. There were 380 local patients and 113 transported patients. The average distance traveled by the local patients was seven miles; the average distance traveled by the transported patients was 85 miles; the median distance was 70 miles.

The distribution of the patients by sex was similar in the two groups. There were 228 males and 152 females in the local group and 67 males and 46 females in the transported group.[2]

TABLE 1.—*Age Distribution of 380 Local Patients and 113 Transported Patients Admitted to the Willard Parker Hospital from June to November 1949*

Age Group, Years	Local Patients		Transported Patients	
	No.	%	No.	%
0- 4	97	25.7	22	19.5
5- 9	111	29.3	44	38.7
10-14	78	20.4	31	27.4
15-19	33	8.6	7	6.3
Over 20	61	16.0	9	8.1
Total	380	100.0	113	100.0

TABLE 2.—*Duration of Illness Before Admission to Willard Parker Hospital*

	Duration of Illness, Days
Local patients	
All	3.3
All dying	3.7
All dying within 24 hours	3.0
Transported patients	
All	3.4
All dying	3.4
All dying within 24 hours	3.5

The age distribution of the patients in the two groups is shown in table 1. The transported group had a greater percentage of patients between 5 and 14 years than the local group. This is to be expected, because in the New York area many children in this age span are sent to camps or taken to vacation resorts for the summer. It will be shown later that the difference in age distribution did not affect the comparability of the two groups.

The averages of the duration of the illnesses in the local group and the transported group are tabulated in table 2. From the time of onset of meningeal symptoms to the time of admission to the Willard Parker Hospital, the average duration of the illness was practically the same in the two groups. The average duration of the illness before admission in all patients who died was 3.7 days for the local patients and 3.4 days for the transported patients. The average duration of the illness in the patients who died within 24 hours after admission was three days for the local group and 3.5 days for the transported group.

To determine whether the more seriously ill patients were selected for transportation at the time the original diagnosis of poliomyelitis was made, information was requested from as many as possible of the doctors who saw the patients at the onset of their illness. Satisfactory data were obtained for 66 of

---

From the Willard Parker Hospital, New York City.

Read before the New York Pediatric Society, March 1, 1950, New York.

[1] Medical inspectors of the Department of Health collected detailed information on all patients with poliomyelitis in New York City. Dr. Morris Greenberg, Director, Bureau of Preventable Diseases, New York City Department of Health, granted permission to review the collected data pertaining to our patients.

[2] $X^2 = 0.017$, standard value 90 per cent $= 0.0158$. The difference between the two groups is such as might occur by chance in about 9 out of 10 instances.

the 113 transported patients. Twenty-six came from an area where there was a small contagious disease hospital. Most of the seriously ill patients (those with bulbar symptoms) and the nonparalytic patients were kept in this hospital. The patients with the following types were sent to the Willard Parker Hospital: nonparalytic 2, spinal 19, bulbospinal 2 and bulbar 3. The percentage of all the patients with bulbar involvement in this group is 19, which is less than in our total group (table 3). Six other patients came from orphanages and were transferred to us as soon as the diagnosis was made. The rest of our patients were on vacation in small communities where local facilities for their care were not adequate. The physicians sent their patients to the hospitals nearest the city of the patient's residence as soon as the diagnosis was made. From the information obtained there is no evidence to indicate that the more seriously ill patients were selected for transportation.

TABLE 3.—*Final Diagnosis for Local and for Transported Patients*

Types of Poliomyelitis	Local Patients No.	Local Patients %	Transported Patients No.	Transported Patients %
Nonparalytic	125	33	22	20
Spinal	177	46	54	48
Bulbospinal	38	10	23	20
Bulbar and encephalitic	40	11	14	12
Total	380	100	113	100

The final diagnosis for each patient was classified as either nonparalytic, spinal, bulbar, bulbospinal or encephalitic poliomyelitis. The final diagnosis was made when the patient was discharged from the hospital or after several weeks of hospitalization. For the transported patient the diagnosis would reflect changes in the course or progression of the disease, including those due to transportation. In table 3 the two groups of patients are tabulated according to the final diagnosis, except that the bulbar and encephalitic types are combined. The percentage incidence of patients with the spinal type was approximately the same in each group. The transported group had a higher incidence of patients with the bulbospinal type and a lower incidence of patients with the nonparalytic type.

The patients with paralytic and encephalitic involvements were observed in the hospital for one to six months. Thirty-eight patients died during this time. Most deaths from poliomyelitis occur within two weeks after the onset of the illness. Thirty-five of our 38 deaths occurred within two weeks. One of the remaining three deaths occurred after 17 days, another after 37 days and the third after 120 days. It has been our experience that some patients who receive respirator treatment die from massive atelectasis following an infection of the upper respiratory tract contracted after discharge from the hospital.[3] However, transportation during the acute stage of the disease would have little bearing on such fatalities.

TABLE 4.—*Fatality Rates in Local and Transported Groups Calculated on Basis of All Patients and Also on Basis of Patients with Bulbar and Encephalitic Involvement*

	Number of Patients	Number of Deaths	Rate of Fatality, Per Cent
All patients			
Local	380	20	5.3
Transported	113	18	16.0
Patients with bulbar and encephalitic involvement			
Local	78	19	24.4
Transported	37	17	46.0

ANALYSIS

Among the 380 local patients there were 20 deaths, a case fatality rate of 5.3 per cent. Among the 113 transported patients there were 18 deaths, a case fatality of 16 per cent (table 4). A fatality rate that is three times greater in one group than in another is obviously significant. However, it seemed advisable to analyze the death rate on a different basis. The nonparalytic and the spinal types of cases contribute little to the fatality rate. Therefore, these were excluded and only those patients with bulbar or encephalitic involvement were used in calculating the fatality rate.[4] All the deaths, except one in each group, were of patients with bulbar or encephalitic involvement. There were 78 such patients, with 19 fatalities in the local group, giving a fatality of 24.4 per cent. In the transported group there were 37 patients, with 17 fatalities, giving a case fatality rate of 46 per cent (table 4). The difference of 21.6 per cent is statistically significant.[5]

In the discussion of the age distribution of our patients, it was noted that there was a predominance of patients between 5 and 14 years of age in the transported group (table 1). To determine whether this difference in the age distribution in our two groups favored a higher fatality rate in the transported patients, we applied the age-specific case fatality rates for the entire city of New York in 1949 (table 5)[6] to each of our age groups (table 1). This gives the expected number of deaths for each age group and the expected total case fatality rate (table 6). The expected case fatality rate by this calculation is higher in the local group, whereas actually it was higher in the transported group. Therefore the difference in age distribution did not favor the higher fatality rate which occurred in our transported patients.

TABLE 5.—*Distribution and Fatality Rates by Age Group of 2,446 Patients with Poliomyelitis in New York City in 1949*

Age Group, Years	Patients Number	Patients Per Cent	Fatality Rate, Per Cent
0- 4	718	29.3	4.2
5- 9	784	32.1	6.1
10-14	415	17.0	5.3
15-19	202	8.3	17.3
Over 20	327	13.4	13.5
Total	2,446	100.0	7.3

TABLE 6.—*Expected Deaths and Fatality Rates in Local and Transported Patients Obtained by Applying Age Specific Case Rates of New York City for 1949*

Age Group, Years	Local Patients No.	Local Patients No. of Expected Deaths	Transported Patients No.	Transported Patients No. of Expected Deaths
0- 4	97	4.07	22	0.92
5- 9	111	6.77	44	2.68
10-14	78	4.13	31	1.64
15-19	33	5.71	7	1.21
Over 20	61	8.24	9	1.22
Total	380	28.9	113	7.7
Expected case fatality rate		7.6%		6.8%

During the first 24 hours after admission to the hospital, four local patients died (20 per cent of the 20 fatalities in this group). During the first 24 hours, nine of the transported patients died (50 per cent of the 18 fatalities in this group). The difference is statistically significant.[7]

COMMENT

The local group and the transported group were found sufficiently similar to permit evaluation of the factor of transportation. The groups were analyzed on the basis of age and sex distribution, the duration of the illness before admission to the Willard Parker Hospital and information obtained from physicians referring the patients to the hospital. It would have been desirable to compare the two groups according to the type or extent of involvement present when the diagnosis was first made. However, sufficient information was not available for the transported patients.

The fatality rate was calculated first on the basis of all patients in each group. The patients who were transported long distances had a fatality rate three times that of the local patients.

Then the fatality rate was calculated for those patients who had bulbar or encephalitic involvement, according to the final diagnosis made in the hospital. On this basis the fatality rate in the transported group was almost twice that in the local group.

The final analysis was of the deaths occurring soon after the patients were admitted to the hospital. The average duration of the illness in the patients who died within 24 hours after admission was practically the same in both groups (table 2). Therefore, this time factor did not affect the fatality rate in the first 24 hours. It seems likely that the greater mortality in the transported group, occurring shortly after admission to the hospital, is due to the long trip during the acute stage.

The harmful effect of physical activity on the severity of poliomyelitis was shown by Russell[8] and by Hargreaves.[9] Russell questioned 44 patients old enough to fix the time of onset of meningeal symptoms and the amount of physical activity, work or play, during the early days of their illness. He found that the amount of physical activity after the onset of meningeal symptoms bore a direct relation to the degree of muscle paralysis. Hargreaves in a similar analysis of 30 cases confirmed the conclusions of Russell. Hargreaves also showed that the maximum exertion in one day after the onset of meningeal symptoms had a more deleterious effect on the prognosis of poliomyelitis than the aggregate of physical activity during the entire period before hospitalization. Recently, Horstmann,[10] in an intensive study of 411 cases from three epidemic areas in this country, confirmed the conclusions of Russell and Hargreaves. Our experience based on fatality rates indicates that long transportation also has a deleterious effect.

Whether the treatment of patients during the acute stage of poliomyelitis should be decentralized or whether the methods of transportation should be improved requires further study.

SUMMARY

Fatality rates are recorded for a group of patients with poliomyelitis who were transported to the hospital over long distances and for a comparable group of patients who were transported short distances. In the same groups the deaths which occurred within 24 hours after admission to the hospital are recorded. All patients with poliomyelitis admitted to the Willard Parker Hospital between June 13 and Oct. 31, 1949 are included. The results indicate that transportation over long distances may be harmful to a patient in the acute stage of poliomyelitis.

SHOULDER-HAND SYNDROME FOLLOWING MYOCARDIAL INFARCTION

TREATMENT BY PROCAINE BLOCK OF THE STELLATE GANGLION

Daniel M. Swan, M.D.
and
John M. McGowan, M.D., Quincy, Mass.

Reflex dystrophy of the upper extremity, often producing serious disability, has been receiving increased attention in recent years. Although the syndrome is due to many different causes, the underlying neurovascular mechanism is probably the same. This paper is concerned with a description of a technic for procaine block of the stellate ganglion using the anterior approach and the results obtained in treatment of the shoulder-hand syndrome following myocardial infarction.

Many cardiologists and other clinicians from Osler[1] on have noted the onset of a painful disability of the shoulder or hand or both following myocardial infarction or long-standing angina pectoris. Libman[2] noted the frequent coexistence of painful shoulder and angina pectoris, but he erroneously attributed the pain to "subacromial bursitis." Ernstene and Kinell,[3] in a study of 133 cases of myocardial infarction, found the occurrence of persistent shoulder pain in 17, and in six of these there was involvement of the hand. In 1943, Johnson[4] published a study of trophic hand changes in 39 of 178 consecutive cases of myocardial infarction, for which he suggested the name "post-infarctional sclerodactylia." In 34 of these cases there was also shoulder pain and disability.

The signs and symptoms of the postmyocardial infarction type of the shoulder-hand syndrome are not specific and resemble those of sympathetic disturbances

---

From the Department of Surgery, Tufts Medical School, Boston, and the Department of Medicine and Surgery, Quincy City Hospital.

Physician in Chief and Cardiologist, Quincy City Hospital (Dr. Swan), and Chief of the Department of General Surgery, Quincy City Hospital; Assistant Professor of Surgery, Tufts Medical School; Visiting Surgeon, Boston City Hospital (Dr. McGowan).

due to other causes. Steinbrocker and associates[5] list the causes of reflex dystrophy of the upper extremity as observed in 42 cases, in the following order of frequency: (1) idiopathic, (2) postmyocardial infarction, (3) post-traumatic, (4) posthemiplegic, (5) postherpetic, (6) diffuse vasculitis, (7) cervical osteoarthritis, (8) panniculitis and (9) gonorrheal arthritis. The mechanism is considered to be one of reflex neurovascular dystrophy, in which the vasomotor and trophic symptoms presumably result from reflex stimulation of the sympathetic nerve supply. Steinbrocker, Spitzer and Friedman[5] state:

> The afferent stimuli may be assumed to arise in a general way from a focus of physiologic irritation or from a local, injured area in the extremity, the heart, the cortex, etc.—any site of external or internal disturbance or violence to tissue. . . . Following a myocardial infarction for example, afferent stimuli traverse the cardiac nerves to enter the cord at levels T_1-T_4. These new and profound stimuli strongly activate the internuncial pool in that area of the cord. The disturbance spreads upward with effects on the anterior horn cells, causing disability of the shoulder muscles. It travels downward to involve the sympathetic neurones of the lateral horn cells innervating the upper extremity.

The clinical course of this syndrome is divided into three stages, which may vary widely in individual cases in duration and symptomatology. The first stage is characterized by painful shoulder disability and stiffness, swelling and pain of the fingers and hand. This usually lasts three to six months. The second stage, which has about the same duration, is characterized by disappearance of the shoulder pain and swelling of the hand. However, stiffness and flexion deformity of the fingers increase, and there may be atrophy of hand muscles and subcutaneous tissues. Roentgenograms reveal osteoporosis of the hand bones. The third stage may continue for months or lead to irreversible changes. Trophic changes in the hand are prominent, and contractures and subluxations may occur. Blood flow in the extremity is diminished, and skin temperature drops.

Treatment of this type of disability in the past consisted primarily of physical therapy, which gave temporary palliation but had little effect on the progress of the disease. High voltage roentgen therapy has been reported as relieving the pain but otherwise not influencing the disability. Interruption of the sympathetic nerve pathways has been reported to give by far the best results. We have used local block therapy by infiltrating the stellate ganglion with procaine hydrochloride (U. S. P.) by the anterior approach, a procedure which has the advantage of necessitating no hospitalization. The sympathetic pathways can be permanently interrupted by surgery if benefit from blocks is not sustained.

It has been shown that in the early stages of the shoulder-hand syndrome there is elevated surface temperature and increased blood flow. Why sympathetic block should be more successful under these conditions than in the later stages is not clear at present, although its success in the later stages, when lowered temperature and trophic changes are present, is easy to understand. This form of therapy breaks up the "vicious circle" which is set up through the internuncial pool of active stimuli in the cord, provoked by the primary etiological condition, and in the majority of cases relieves the pain, muscle spasm and disability.

METHODS AND TECHNIC

The method of stellate procaine block used is one developed and used by one of us (J. M. M.) over the past six years. It has been used in treatment of various sympathetic and vascular disturbances such as causalgia, frostbite, thrombophlebitis, Raynaud's disease and cerebrovascular accident. These blocks were generally carried out as office and clinic procedures. However, it is advisable that one have on hand oxygen that can be administered with a B. L. B. mask and bag or some similar apparatus, in order that the patient may be kept on continuous artificial respiration for a period of one hour in case some of the procaine finds its way into the spinal canal.

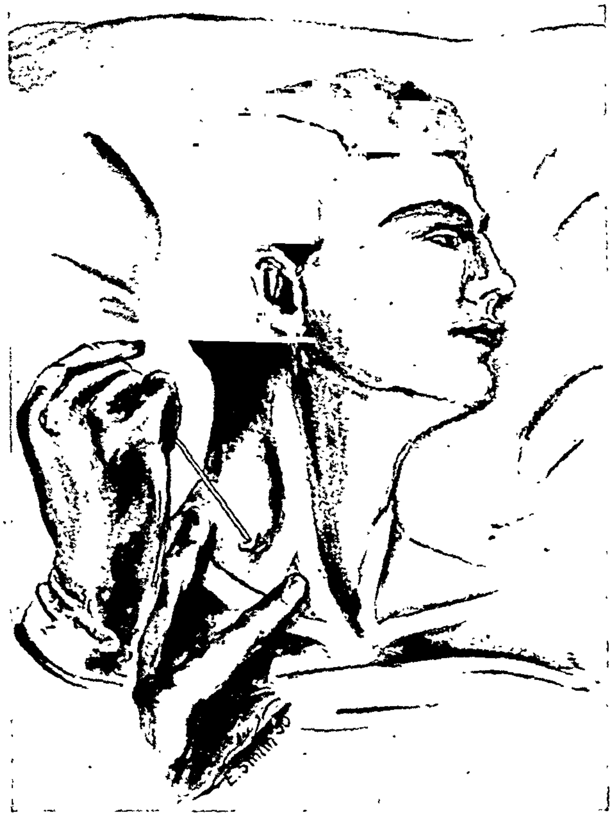

Fig. 1.—General direction in which the needle is inserted through the scalenus anticus muscle in order to strike the transverse processes of the lower cervical vertebrae.

The head is turned away from the side to be treated and is hyperextended. A procaine wheal is raised 1 fingerbreadth above the clavicle over the center of the scalenus anticus

muscle just lateral to the clavicular portion of the sternocleidomastoid muscle. The index and middle fingers of the left hand are placed one on each side of the scalenus anticus muscle (fig. 1). A 24 gage 2 inch (5 cm.) needle is placed on a 20 cc. Luer-Lok syringe containing 15 cc. of 1 per cent procaine hydrochloride solution. This needle is then inserted through the wheal and is pointed in a direction inward and downward so as to aim in the general direction of the transverse processes of the lower cervical vertebrae or the neck of the first rib. This needle is inserted until it strikes bone at a depth of approximately 5 cm. During insertion of this needle, a continuous injection of procaine is made in order to produce a painless tract along which the second needle can be passed without discomfort to the patient. A regular 19 gage, 3½ inch (9 cm.) spinal needle is passed in the same general direction until it strikes bone at approximately 5 cm. from the skin level. The needle is passed directly through the scalenus anticus muscle between the index and the middle finger, which still straddle this muscle (fig. 2). The needle is directed inward, backward and caudad until it strikes bone. The stylet is then withdrawn, and a few moments is spent observing the needle for evidence of leakage of spinal fluid. If the needle is inserted too far, it is possible that it might pass through one of the intervertebral foramens into the spinal canal, or occasionally there may be an extension of the dura along the spinal nerve roots into which the tip of the needle may be inserted. The needle should then be rotated 180 degrees, and one should again wait for evidence of spinal fluid. If none is found or if there is no blood, the needle should then be rotated to its original position and an empty syringe attached and aspiration made. If no blood or spinal fluid is obtained, then one should inject 10 cc. of a 1 per cent procaine hydrochloride solution slowly.

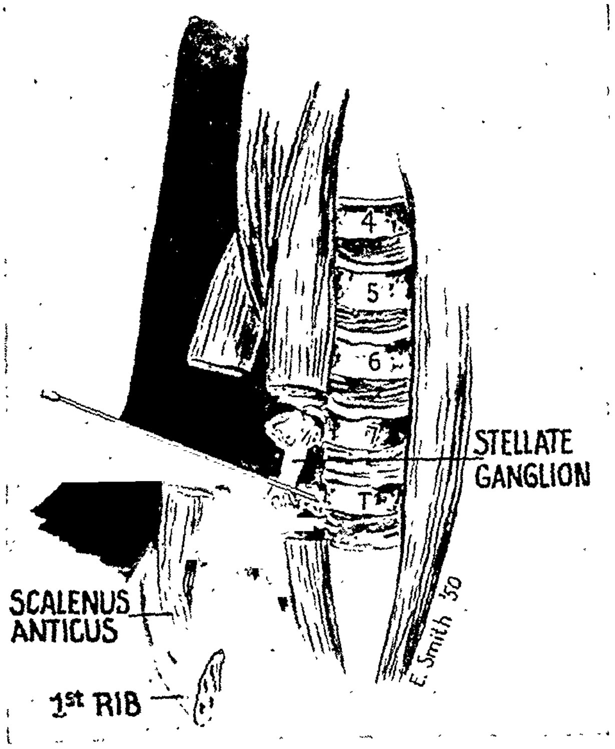

Fig. 2.—Relationship of the stellate ganglion to the transverse process of the cervical vertebrae, the neck of the first rib and the scalenus anticus muscle.

The principle of this technic is based on the fact that the sympathetic chain which contains the stellate ganglion is closely attached to the prevertebral fascia. This fascia, in turn, lies only a very short distance in front of the vertebral bodies and transverse processes. The injected procaine flows up and down behind the prevertebral fascia and is bound to strike that ganglion, since it has no other place it can go (fig. 3).

The patient should be carefully observed for a 15 minute period for any evidence of leakage of procaine into the spinal canal. After this injection, Horner's syndrome develops—i. e. the pupil constricts, the eyeball recedes into the head, the upper lid droops and there is absence of sweating on the right side of the face and head. The hand and arm on the treated side also become considerably warmer than the opposite extremity.

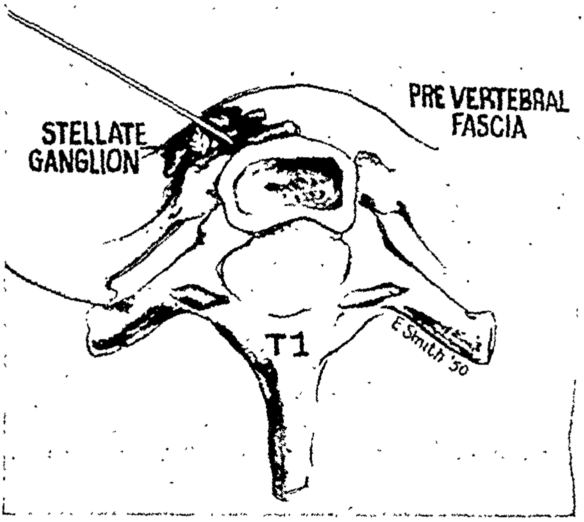

Fig. 3.—Relationship of the stellate ganglion to the prevertebral muscles and prevertebral fascia and the manner in which the procaine solution spreads forward to the prevertebral facia, to which the stellate ganglion is closely attached.

RESULTS

Within 10 minutes after injection of the stellate ganglion with procaine, there was complete relief of pain in the shoulder and arm and also in one case there was relief of a pain in the precordial region which the patient had complained of constantly. More striking, even, than the relief of pain was the remarkable return of function in the muscles of the extremity. Prior to treatment, these patients were unable to use the involved extremity. The muscles were in a chronic state of spasm. This spasm was so severe that it was very difficult for the patient to raise the arm, move the elbow or open and close the hand. The spasm was different from that which is observed in muscles in other conditions, in that the patient could move the muscles but with a great deal of difficulty, like the stretching of some inert semielastic plastic substance. After the procaine block of the stellate ganglion, each patient was able to open and close the hand with facility and also move the arm at the shoulder and elbow. One of these patients had been unable to raise his hand off the bed for three months. Ten minutes after the first procaine block, he was able to move the hand and arm with a remarkable degree of facility, and after the third injection he was able to return to his work, which involved the handling of precision instruments, a task that he had not been able to do for nearly a year.

Another patient was more impressed with the relief of stiffness of the hands than with the relief of pain.

Whenever he tried to open and close his hand, it appeared as if there was a pronounced stiffness in the joints of the fingers. On closer observation, it was determined that his stiffness was due to an inability of the muscles to relax. After the first treatment the patient was able to open and close the hand in a normal manner.

REPORT OF CASES

CASE 1.—Mrs. J. T., a 56 year old housewife, in March 1948 had an episode of severe chest pain and dyspnea, after which she was hospitalized for five weeks. Soon after discharge, she began to notice pain and stiffness in the left hand, arm and shoulder and also sharp pain radiating across the left upper part of the chest and to the left scapula and neck, not related to exertion. When she was seen in November 1948, these symptoms were persistent and marked. On examination there was pain on motion and limitation of flexion of the fingers of the left hand. The deep reflexes were equal and active. An electrocardiogram was consistent with coronary artery disease with old anterior myocardial infarction. She received three left stellate ganglion blocks over a period of one month, each of which was followed by Horner's syndrome, increased warmth, increased mobility and relief of pain in the left hand and shoulder. There was also relief of the chest pain. The swelling of the fingers receded. At the time of this writing (January 1950), almost two years later, there is continued relief from pain and markedly improved mobility of the shoulder and flexibility of the fingers. An excerpt from a letter in reply to a follow-up note reads as follows: "Dec. 29, 1949. I am grateful to you for your interest in my case and for the relief from pain that your treatments have brought me. Since the last one, on Jan. 4, 1949, the pain in the left shoulder gradually decreased until June. I was able to move my arm around to my back. Now I have complete freedom of action of my arm without pain. The swelling of the left hand went down very soon after treatment, and the redness and pain in the knuckles have greatly diminished. My right hand also benefited. A year ago both hands were painful and stiff, but now I can close them with a minimum of pain."

CASE 2.—H. C., a 63 year old retired Navy petty officer, in July 1948 had an attack of prolonged substernal pain and dyspnea while building a house. An electrocardiogram was consistent with a recent coronary thrombosis with anterior myocardial infarction. He was kept in bed for four weeks. Eight weeks after the attack he began to notice pain and disability in the right shoulder and hand. On examination there were limitation of abduction and pain on motion of the right shoulder, the patient being unable to put on a coat without assistance. There was limitation of both flexion and extension of the fingers of the right hand but no swelling or color changes. There were no reflex changes. These symptoms and signs persisted, and in December 1948 he received three right stellate ganglion blocks at weekly intervals. After these, there were definite relief of pain and increased mobility in the right shoulder and fingers, although he continued to complain of occasional mild aching and stiffness of the fingers until his death, from recurrent coronary thrombosis, in November 1949.

CASE 3.—J. A. P., a 61 year old factory worker, was hospitalized on April 12, 1948, because of prolonged substernal pain. There was a preceding eight year history of exertional angina pectoris relieved by glyceryl trinitrate. An electrocardiogram was interpreted as indicating a coronary thrombosis with recent anterior myocardial infarction. His course was uneventful for three weeks, when he noted the onset of pain and stiffness in the right wrist and shoulder. This was followed by pain, erythema and swelling of the fingers and dorsum of the right hand; the pain was severe and required narcotics for control. The swelling and pain gradually subsided but on discharge on June 1, the patient had marked limitation of abduction of the shoulder and of flexion of the fingers. He returned to work in October but was unable to perform his previous duties because of right shoulder and hand disability. In December he noted the onset of painful disability of the left shoulder and left hand. He was hospitalized again, in January 1949, because of recurrent substernal pain. An electrocardiogram suggested an old anterior myocardial infarction. Examination revealed painful limitation of motion of both shoulders, the patient being unable to raise either arm more than 30 degrees while recumbent. There was limitation of flexion of the fingers of both hands. Roentgenograms revealed deossification about the right shoulder girdle, most marked in the head of the humerus, and about the articular surfaces of the carpals, metacarpals and phalanges of the right hand. He received four stellate ganglion blocks on the left and one on the right and was discharged with increased mobility and relief of pain in both hands and shoulders. He returned to work in June 1949 and at that time was able to raise both arms vertically over his head and to clench his fists satisfactorily.

SUMMARY AND CONCLUSIONS

1. The shoulder-hand syndrome occurs in approximately 10 to 20 per cent of cases of myocardial infarction. The degree of disability reported has been variable: in some cases it has been described as minor; in other cases it has been extremely severe, leading to serious incapacity and inability of the patient to perform useful work.

2. Formerly, treatment recommended for this condition included physical therapy, roentgen treatments, ganglionectomy and periarterial sympathectomy. A sufficient number of cases of procaine block of the stellate ganglion have been reported in the literature to indicate the beneficial results of this treatment.

3. In this paper we have reported the results of treatment of a series of patients with shoulder-hand syndrome by stellate block with procaine hydrochloride by the anterior approach. This method is considered to be fairly simple and is consistently successful when employed with a reasonable amount of skill. The results have been excellent in every case.

The Need for Malaria Control.—Malaria still ranks high in the list of man's afflictions and it remains a crippling reality to vast numbers of people in warmer lands. As we become more and more involved in such areas, through military and "Point Four" activities, we may expect the importance of overseas malaria to become clearer. We shall also have to be watchful against imported malaria and its possible spread in the United States for many years to come. There was very little spread in this country of the malaria contracted overseas in World War II because we were so well prepared to prevent it. But one should not assume, as too many do, that DDT has solved all the problems, and that it is illogical for scientists to pay more attention to this disease, needless for sanitary engineers to have further concern over adjusting the environment to prevent anopheline breeding, and wasteful for administrators to budget funds for malaria studies. Paul F. Russell, M.D., Malaria and Society, *Journal of the National Malaria Society*, March 1951.

IMPORTANCE OF BRONCHIAL INVOLVEMENT IN PRIMARY TUBERCULOSIS OF CHILDHOOD

Herman I. Laff, M.D., Allan Hurst, M.D.
and
Arthur Robinson, M.D., Denver

Recognition of the importance of bronchial affections in adult pulmonary tuberculosis has been attained by an increased utilization of bronchoscopy during the past two decades that has added immeasurably to our knowledge of this disease. In the forefront of the contributors to this subject have stood American bronchoscopists trained in the tradition of Chevalier Jackson. Bronchial involvement in childhood pulmonary tuberculosis is similarly important but appears to have received less attention among bronchoscopists in this country.

The foreign literature has been far more replete with articles dealing either with exhaustive studies or with isolated case reports than has the American literature. In reviewing the *Transactions of the American Broncho-Esophagological Association* we have been able to find only one contribution, that of Myerson [1] in 1940. During the past five years numerous articles in foreign periodicals have been listed,[2] with scarcely a reference by American authors. The few papers in this country have for the most part recorded institutional experiences.[3]

Pediatricians and physicians in private practice have apparently been reluctant to subject infants and young children with primary tuberculosis to bronchoscopic investigations, mainly due to the rigors and dangers still associated with this examination. It would also appear that the relatively benign and frequently asymptomatic character of some of the cases has not directed attention to them. By contrast, the hazards of bronchial compression and perforation by hilar nodes have not often been appreciated. It is possible that bronchoscopists have also failed to recognize and evaluate the presenting disease in the small bronchi of infants, especially when the examinations were not made with sufficiently adequate anesthesia to permit an accurate interpretation.

Our attention was focused sharply on this problem quite by accident when our first patient (case 1) was referred to one of us for bronchoscopic examination because of symptoms suggestive of foreign body aspiration (cough, wheezing and x-ray signs of lobar atelectasis). The caseous masses removed during bronchoscopic treatment were subsequently proved to be the extruded contents of hilar tuberculous nodes that had perforated through the bronchial wall. It is unfortunate that only a minority of these children manifest signs of aspirated foreign body. Otherwise, many now overlooked would be referred for treatment with the bronchoscope.

Since the burden of definitive diagnosis and treatment must ultimately fall on the bronchoscopist, a review of some of the salient problems of primary pulmonary tuberculosis of childhood as it relates to concomitant bronchial involvement is in order. Students of this disease have long been impressed by the variability of roentgenologic patterns and by the frequent discrepancy between the relatively large amount of pulmonary parenchymal involvement as shown by x-ray and the paucity of clinical symptoms in many cases. Two roentgen patterns in particular have been disturbing: viz., the relatively common lobar or wedge-shaped densities formerly called epituberculosis and now variously interpreted as pneumonitis or atelectasis, and the less common pattern of obstructive emphysema. On the basis of our experience we wish to concur with those who stress that these shadows are not primarily infiltrations but are most commonly the result of extrinsic or intrinsic involvement of the bronchi by the tuberculous process.

In presenting the following cases we are endeavoring to give examples of the involvement of the bronchus in different types of primary tuberculosis. In our series many patients showed roentgen signs of atelectasis, emphysema or both. In some where x-ray signs of atelectasis or obstructive emphysema were present the symptoms associated with these states, such as cough and wheezing, were frequently absent.

REPORT OF CASES

CASE 1.—M. A. J., a white girl 19 months old, began to cough and wheeze after having had measles. An x-ray was taken some months later and a partial atelectasis of the right lower lung field was noted. Because of suspicion of the presence of a foreign body one of us (H. I. L.) treated her with the bronchoscope and found some inspissated, cheesy particles in the right main bronchus. The atelectasis cleared but reappeared one month later, and due to the diagnosis of tuberculosis the patient was admitted to National Jewish Hospital in Denver. Obstructive emphysema of the entire right lung was observed, both clinically and on roentgenogram. The gastric washings were positive for acid-fast organisms. A bronchoscopic examination again revealed masses of caseous material in the right main bronchus that were aspirated with improvement. Two months later, with recurrence of the emphysema, she was again treated with the bronchoscope, with aspiration of the same material, positive on culture for Mycobacterium tuberculosis but negative on smear. Two weeks later a bronchoscopic examination showed a small opening in the lateral wall of the right main bronchus with a small mass of caseous material partially occluding it. The mucous membrane was edematous but appeared improved. From that time on the

W.: Late Non-Tuberculous Complications of Calcified Hilar Lymph Nodes, Am. Rev. Tuberc. **60**:1, 1949.

child showed improvement, but six months later, with the reappearance of physical signs, a granulation was found on the anterior wall of the right main bronchus immediately over the opening of the right middle lobe bronchus. In all, the child has been treated with the bronchoscope 10 times and is now clinically well.

Case 2.—C. H., an 8 year old white boy, had symptoms of weight loss, night sweats and irritability for three months prior to admission. On admission a pneumonic consolidation was noted in the right upper lobe. Bronchoscopic examination done a few days after admission showed definite caseous material in the right upper lobe branch, and after aspirating portions a granulomatous-appearing mass was also noted. The aspirated material was negative on smear but positive for tubercle bacilli on culture. Repeat roentgenography showed distinct clearing of the consolidation.

Case 3.—G. G., a Spanish-American boy 5 years old, became ill with signs and symptoms of left upper lobe pneumonia and was admitted to National Jewish Hospital some months later. The left upper lobe was dense on roentgenogram, and tomograms revealed the left upper lobe bronchus to be completely obstructed, ending in a blind pouch. Bronchoscopic examination disclosed that the opening of the left upper lobe bronchus had swollen, rounded margins with edematous mucous membrane. The lumen was plugged by caseous material that was found positive on culture. Further bronchoscopic examinations resulted in aspiration of a similar substance, and at the last examination the bronchus was narrowed with an inward bulging of the posterior wall. There was distinct clearing of the consolidation on roentgenogram.

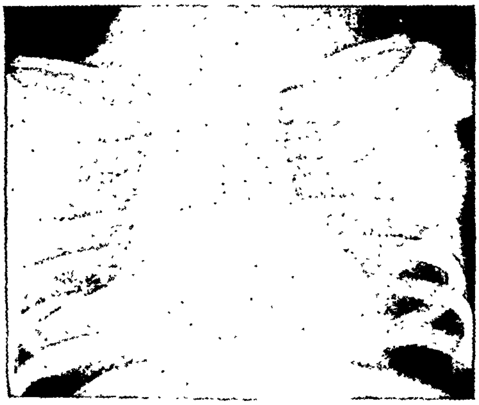

Fig. 1 (case 1).—Atelectasis of right lower lobe.

Case 4.—J. M., a Spanish-American boy, 10 months old, was admitted because of suspected disseminated tuberculosis. Roentgenogram showed a contracted left lung with shift of the mediastinum to that side, and some obstructive process was suspected. Although the first bronchoscopic examination was negative, a repeat examination done one month later showed the carina thickened, the left upper lobe branch orifice the site of a granuloma and some caseous material. This was aspirated and found negative for tubercle bacilli on smear and culture. Further bronchoscopic examinations were negative, and roentgen examination showed progressive improvement.

Case 5.—B. L. R., a Spanish-American girl, 3½ years old, had been hospitalized with a positive chest roentgen finding after a contact examination. For almost a year there was no remarkable change in the lesion in the right lower lung field, and bronchoscopic examination was done as a diagnostic procedure. Examination showed a fistulous opening surrounded by a granuloma in the anterior wall of the right main bronchus near the upper lobe orifice. One month later examination with the bronchoscope revealed caseous material in the right main bronchus positive on culture. There has been progressive clearing of the roentgen findings since that time. It should be noted that at no time were there the classical symptoms or signs of bronchial obstruction.

COMMENT

As suggested by a study of the cases presented, it is well to recognize that the consolidations of primary tuberculosis are commonly of two types: (1) benign-asymptomatic and self-limited, the more frequent variety, and (2) malignant, complicated by progressive tuberculous pneumonitis, not infrequently fatal. The roentgen patterns of both varieties may be indistinguishable, and indeed there is good evidence that both conditions may have the same pathogenesis.

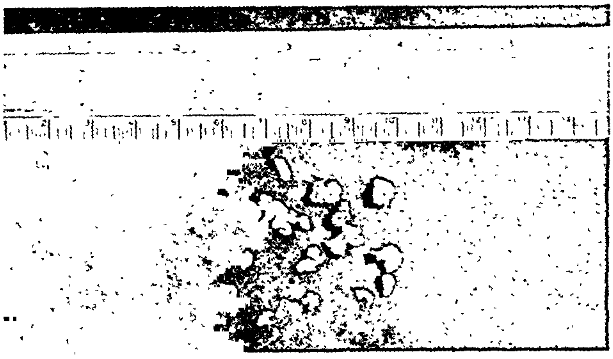

Fig. 2 (case 1).—Particles of caseous material removed during bronchoscopic examination. Corresponding amounts were removed at three subsequent examinations.

Oppenheimer[4] has shown that the majority of instances of tuberculous "pneumonitis" in the younger age group are the result of aspiration into the bronchi of caseous material. In most cases such material contains few viable organisms and many dead ones, and there results a resolving type of absorption atelectasis and pneumonitis (type 1). Rich claims that whether rupture of a caseous lymph node into a bronchus will cause progressively fatal disease or the so-called benign type depends on the concentration of live tubercle bacilli in the caseous material as well as on host resistance. He has been able to duplicate both these types of tuberculous disease experimentally in animals.

In short, the experimental, clinical and pathological evidence all lead to the conclusion that many of the extensive parenchymal consolidations of primary tuberculosis are a combination of absorption collapse and tuberculous pneumonitis stemming mostly from bronchial obstruction and varying degrees of involvement of the bronchial wall. Whether the bronchial obstruction

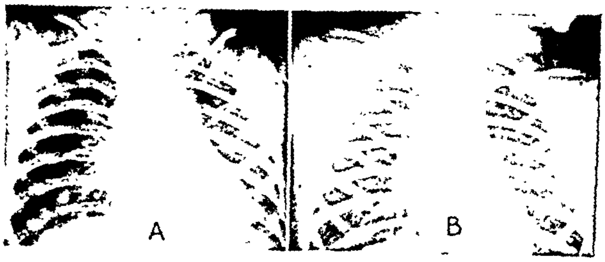

Fig. 3 (case 1).—*A*, distinct obstructive emphysema of the left lung within six weeks; *B*, normal aeration after aspiration of caseous material.

[4] Oppenheimer, E. H.: Experimental Studies on the Pathogenesis of Epituberculosis, Bull. Johns Hopkins Hosp. 57:247, 1935; cited by Rich, A.: The Pathogenesis of Tuberculosis. Springfield, Ill., Charles C Thomas, Publisher, 1946.

is caused by pressure from enlarged nodes, contiguous invasion of the bronchial wall with true development of endobronchial disease or by actual plugging of stem, lobar or segmental bronchi with caseous material, a valvular mechanism is developed that leads to obstructive emphysema or obstructive atelectasis, reflecting variations in the degree of bronchial obstruction.

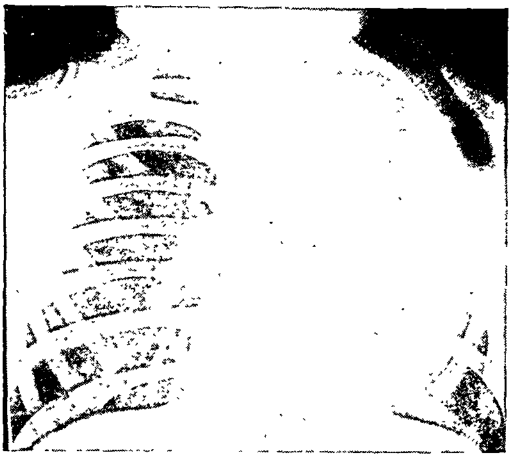

Fig. 4 (case 3).—Extensive density involving the left upper lobe.

The clinical importance of these observations is great. In spite of Rich's contention that the condition is more than an atelectasis carrying with it a varying amount of pneumonitis, the results of bronchoscopic aspiration with rapid clearing in many cases would tend to throw considerable weight in the direction of obstruction.

As to the clinical findings, all observers are agreed that they are not in proportion to the roentgen pattern. While the child may have been initially slightly ill, the temperature is usually normal or low grade. The cough may occasionally be spasmodic and resembles that of pertussis. Wheezing may be intermittent or constant, but on physical examination its location is usually constant. Again it must be stressed that "all is not asthma that wheezes." One important symptom is the rattling or whistling of the lungs during expiration. Unless treatment is instituted this picture may persist for months or even years, thus paving the way for irreversible change and the elements of chronicity.

There appears to be a difference of opinion as to how much of this condition may be due to extrinsic pressure on the bronchi or due to extension into and rupture through the bronchial wall. It is our feeling that all stages, from one extreme to the other, frequently occur, and that actual bronchial rupture is much commoner than we have hitherto been led to suspect.

Myerson,[1] reporting on a series of 29 tuberculous children treated with the bronchoscope, found bronchial rupture in only one and evidence of bronchial compression, by enlarged nodes, in seven. Our own series consisted of 15 cases of primary tuberculosis with either wheezing or persistent atypical x-ray shadows. These have been treated during the past 18 months, and we aspirated caseous material from seven, 47 per cent of the total group studied. While the actual point of rupture could not always be visualized at the first bronchoscopic examination, it could usually be demonstrated at subsequent examinations, and there could be little doubt that this was the source of the aspirated caseous material. It is our feeling that repeated examinations with the bronchoscope will ultimately demonstrate rupture in an increasingly greater percentage of cases studied.

Görgényi-Göttche and Kassay [5] were able to demonstrate bronchial rupture in 18 out of 28 patients given bronchoscopic treatment. They were able to substantiate by tomography that most infections in their patients were due to intramural bronchial obstruction rather than stenosis by external pressure. As confirmatory evidence they found bronchial rupture in eight of 17 consecutive autopsies on tuberculous children. Only one half of these were so located that they could have been seen on bronchoscopic examination. This is obviously significant, since a negative examination does not exclude the possibility that rupture has occurred into the smaller bronchi. Similarly, Rich has observed many instances at autopsies of healed bronchial perforations in adult persons dying of nontuberculous cause. His feeling is that these lesions would be found with much greater frequency if special search were made for them.

Recently Richards [6] reported that an atelectatic process developed in 21 per cent of 239 children under 6 years of age with primary tuberculosis. Over 6 years of age the percentage was less. On bronchoscopic examination the commonest cause he could find was the narrowing of the bronchi due to extrinsic pressure. In a series of 28 cases of active primary tuberculosis associated with radiographic abnormalities in the lung field Hutchinson [7] found that only two patients had no bronchoscopic evidence of obstruction. Of the 26 patients with positive bronchoscopic findings only nine showed solely extrinsic pressure on the bronchus by enlarged lymph nodes.

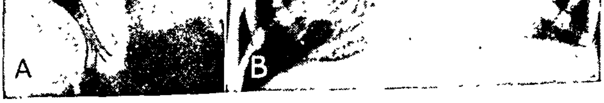

Fig. 5 (case 3).—*A*, tomogram showing the left main bronchus with the upper lobe branch ending in a blind pouch; *B*, distinct clearing on the left after several bronchoscopic examinations.

Jones, Rafferty and Willis [3b] examined 42 children with benign parenchymal tuberculosis. In only 11 did the bronchial tree seem normal. Aspiration, cauterization and biopsy resulted in the clearing of the process in more than one half of the patients. They actually found atelectasis in more than 12 per cent of children with primary tuberculosis.

Encroachment on the bronchi by enlarged lymph nodes can be considered the forerunner to rupture. Careful inspection may sometimes reveal the caseous contents shimmering through the thinned mucous membranes. The process has been likened to the coalescence of tuberculous nodes in the neck with the adjacent skin ultimately being necrotic as a manifestation of nature's effort to be rid of the caseous contents. In the bronchi there may be multiple points of rupture, not necessarily discerned simultaneously. The rupture may be pinpoint in size or quite large. In the latter condition, where large caseous masses may be extruded, fatal impaction in the trachea and larynx may result in asphyxia. One such case was reported recently.[8]

When the caseous material is extruded in small pieces it is usually removed by coughing. Frequently masses of such material become lodged in bronchi and if not expelled will produce obstructive emphysema, atelectasis and ultimately bronchiectasis with supervening infection in the segment or lobe plugged. Granulations and tuberculomas may be found adjacent to the site of rupture. These, of course, add to the obstructive phenomena and should be removed.

The picture of bronchial invasion in childhood tuberculosis differs from that in adults. When the caseous portion of the node is expelled healing takes place with a minimum of scarring and very little narrowing of the bronchus. In adults the ulcerogranulomatous masses of tuberculous tissue tend ultimately to surround the entire circumference of the lumen of the bronchus involved, and when healing occurs the resulting fibrosis produces distinct and permanent stenosis. Fortunately, streptomycin has been found to hasten resolution and lessen the stenotic tendency if adequately administered.[9] In our own experience with rupture of tuberculous nodes in children streptomycin is of little benefit in accelerating healing or terminating the process. This may be because it exerts a favorable effect only on the inflammatory tissue adjacent to the point of perforation.

At bronchoscopic examination the effect of bronchial compression will be evidenced by widening of the carina, narrowing and distortion of the bronchial lumens and widening of the spurs between the bronchial orifices. Since compression precedes rupture, the former is more commonly present. For proper detection and evaluation of narrowed bronchi in infants it is our contention that bronchoscopic inspection is best made under general anesthesia. The uncontrollable motions of the bronchial wall that result from coughing and squeezing will otherwise be very difficult and confusing for accurate interpretation. Those who advocate bronchoscopic treatment in infants and children without anesthesia are usually associated with large bronchoscopic clinics. They have the advantages of teamwork and well trained personnel, which admittedly may compensate for the deficiences of examination without anesthesia. However, we have seen no deleterious aftereffect from administration of ether anesthesia to these children. There was no clinical or x-ray evidence of spread after bronchoscopic treatment and only occasional minor rise in temperature. Appreciable subglottic edema has not occurred, as we have been very careful to use small bronchoscopic tubes.

We have also preferred the proximally lighted bronchoscope to the Jackson type instrument mainly because of the superior over-all view permitted by the former. Study of relationships is very important for adequate diagnostic impressions, and the over-all view allowed by this instrument is appreciated in the small bronchi of infants. It should be noted that strong suction may hasten rupture and emptying of the nodes. We have observed this sequence with persistent use of suction in bronchi that were first seen narrowed by extrinsic pressure and later yielded caseous material. There has been relatively little bleeding after aspiration of the necrotic masses, and it has not seemed a hazardous procedure.

Permanent atelectasis with or without bronchiectasis [3c] has been demonstrated in several series of cases studied. The "middle lobe syndrome" [10] has been amply proved as related to healed primary tuberculous infection in the majority of cases. Broncholiths,[3d] the calcified masses of healed tuberculous lymph nodes, with the constant attendance of hemoptysis are but another proof of the importance of the healed primary infection and its complications. Obstructive emphysema of varying extent may be just as significant a lung-destroying process as severe pulmonary suppuration.

Regarding its value in treatment, it is our feeling that repeated treatment with the bronchoscope may prevent or mitigate such late complications. While it is true that many children seem to get well without therapy, the incidence of late complications has not been adequately checked. In any case, where there is even slight evidence of segmental, lobar or massive lung involvement bronchoscopic treatment should be done as a diagnostic procedure. The pattern may be that of atelectasis or emphysema and may vary from one extreme to the other in the same patient. Neither x-ray nor clinical evidence can differentiate extrinsic pressure from perforation of the bronchial wall. Should caseous material be found it should be aspirated, and such aspiration should be repeated at frequent intervals. Removal of material improves the airway and prevents passage into smaller bronchi, hence treatment with the bronchoscope becomes an important therapeutic procedure in such cases. Streptomycin and paraaminosalicylic acid (PAS) should be given, since evidence in adults indicates that it relieves edema and that it may effect the course of childhood tuberculosis favorably. When simple extrinsic pressure of nodes is found treatment should be expectant, and bronchoscopic treatment must be repeated at intervals, watching for rupture and aspiration should it be necessary.

SUMMARY

1. Bronchial involvement in the pathogenesis of parenchymal consolidation and in the course of primary tuberculosis in children is an important and frequently overlooked factor.

2. Not only should bronchoscopic treatment be done in patients presenting evidence of wheezing, atelectasis or obstructive emphysema but in every patient with childhood primary pulmonary tuberculosis whose progress is not considered satisfactory.

3. The relative ease and safety of bronchoscopic examination in such patients is stressed, as well as some of the complications found in later life that might be averted.

ABSTRACT OF DISCUSSION

DR. MERVIN C. MYERSON, Beverly Hills, Calif.: The paper that was read is not exactly the same as the paper that was submitted to me. Dr. Laff and his associates stressed the fact that there are many more foreign articles than American articles. I think it is fair to say that the American physicians are more considerate of their children as patients, and, after all, treatment with the bronchoscope and the laryngoscope are not playtime activities for these youngsters. Despite the fact that Dr. Laff and his associates have not had difficulty with ether anesthetic, it is my opinion that it is not without danger. These children are entitled to an anesthetic. As long as thiopental sodium (pentothal® sodium) is available we should use it. Thiopental sodium can be used if as a child is being anesthetized the larynx is under laryngoscopy; then the bronchoscope can be readily passed. There is no difficulty whatsoever. The lesions that have been mentioned seemed to have been based on the impression gotten from an article written by Rich in which he states that all bronchial lesions encountered during bronchoscopic treatment are due to glands that either compress the bronchus or penetrate it. The word "rupture" to designate a pin point opening into the bronchial gland is unsatisfactory. I would rather use the word "penetration." Among children one encounters three types of lesions. A great preponderance comes under the heading of involved glands. These lymph nodes occur in three places: below the carina, or inter-bronchial angle, and at the right and left tracheobronchial angles. Another effect of prolonged compression from glands is malacia, a softening of the bronchial wall so that the cartilaginous rings are absorbed, and when bronchoscopy is done a horizontal slit is seen. This is especially noted on the left side. The other two types are pulmonary lesions and endobronchial lesions. These are always secondary to parenchymal lesions. Dr. Laff mentions the postmortem changes in these cases. I would warn that postmortem changes in the tracheobronchial tree in tuberculosis are never indicative of the true condition before death. If one treats a patient bronchoscopically 24 hours before he dies and later looks at the autopsy specimens he is astonished at the extent of pathological change that occurred during those 24 hours. There is a tendency on the part of bronchoscopists to use the word "edema." I want to ask Dr. Laff what he means when he speaks of "edema." There are two types of edema: edema of passive congestion, pressure on the venous return flow, and edema due to the inflammatory process. In the long-standing tuberculous lesions one does not get edema unless there is an acute pressure or an acute inflammatory process.

DR. PAUL C. SAMSON, Oakland, Calif.: Dr. Laff and Dr. Myerson have suggested that bronchial complications frequently develop during a primary tuberculous infection in childhood and are often overlooked. I am in complete accord with these observations. One has but to study the additional reports of Jones, Rafferty and Willis, and Kent to gain further insight into the problem. It is of great importance to recognize the essential pathological condition of so-called "epituberculosis" and to realize that in most instances the primary disturbance is bronchial rather than pulmonary. If this concept is accepted it becomes obvious that bronchoscopic treatment is a necessary procedure both from the diagnostic standpoint and from the therapeutic standpoint. It should be emphasized that signs, symptoms and roentgen findings frequently cannot be correlated, that investigation of all three aspects is necessary, and that any suspicion of impaired bronchial function warrants bronchoscopic exploration. The type of bronchial obstruction observed is of considerable interest. Those with greatest experience report a preponderance of patients in whom the bronchial obstruction is due to caseous debris from ruptured peribronchial lymph nodes. Granuloulcerative lesions identical with those seen in adult tuberculous tracheobronchitis have been observed, however. In the latter group particularly I believe there is every justification for short-time but intensive antimicrobial therapy. The value of early and, perhaps, repeated bronchoscopic aspirations is emphasized by a number of observations to the effect that under these conditions the pulmonary lesions clear much more promptly. This should give the child a chance for a speedier recovery and reduce the chances of the development of: (1) progressive tuberculous pneumonitis, which is not infrequently fatal, and (2) irreversible bronchopulmonary change. In regard to the latter hazard, it is interesting to speculate on the possibility of future nontuberculous disability. Bronchial stenosis certainly develops on occasion, as does permanent bronchiectasis. Kent proved the presence of bronchiectasis in seven of a total of 10 children whom he examined but noted that infected, i. e., symptomatic, bronchiectasis did not develop during a short period of observation. It is a known fact, however, that symptoms develop in many of these children sooner or later. In retrospect, it is probable that a goodly number of patients with the so-called "middle lobe syndrome" can blame their difficulties on an early epituberculosis with bronchial obstruction. In my experience with 25 patients with isolated right middle lobe obstructive pneumonitis, approximately 25 per cent showed concomitant bronchial obstruction and peribronchial calcified lymph nodes. There is the small but appreciable group of patients whose symptoms are due to broncholiths. This group recently has been investigated by both Head and Schmidt. These patients would seem to be suffering from a nontuberculous complication of an earlier acid-fast infection. In children, suggestive clinical and/or roentgen signs of impaired bronchial function should make early and frequent bronchoscopic examinations mandatory to the end that (1) an unquestioned diagnosis be established; (2) early restoration of a normal parenchyma and bronchus be made more certain, and (3) the later nontuberculous complications of bronchial stenosis, bronchiectasis and broncholiths be minimized.

DR. W. L. HOWARD, Detroit: I would like to refer to a series of 59 cases of epituberculosis in children hospitalized at the William H. Maybury Sanatorium (Detroit Municipal Tuberculosis Sanitorium), Northville, Mich., in which bronchoscopic examination was done. Seventy-four per cent of these cases showed abnormal findings, the variety of which is shown by the following list: bulging of the bronchial wall from extrinsic pressure, tuberculoma, endobronchial ulceration, mucosal swelling, rupture of caseous node through the bronchial wall. We felt also that thick secretions must also be listed as a factor in the bronchial obstruction in very small children. We feel that treatment with the bronchoscope can be done in all but very small babies and recommend that it be used routinely. Review of 32 of these children nine years after their hospital treatment showed evidence of bronchiectasis in 70 per cent. The question whether to use streptomycin in treating these patients is important. Our observations show that, although the effect of streptomycin on the enlarged nodes is very slight, there is a good improvement in the resolution rate in the parenchymal portion of the lesion, and we feel that the use of streptomycin may be expected to reduce materially the incidence of bronchiectasis in these cases. In addition, it was noted that although the tendency to spread is very great no spreads were observed in the treated children. We are not yet certain that streptomycin will actually prevent the development of bronchiectasis but hope that a further period of observation will show this to be true.

DR. HERMAN I. LAFF, Denver: My enthusiasm for this subject stems from the fact that I diagnosed my first case only 18 months ago, although I have been doing a good many bronchoscopic examinations on tuberculous patients during the past 20 years. I have found evidences of nodes invading and perforating the bronchi of tuberculous adults not infrequently. The predominance of this type in children, however, has always been stressed in the literature. I am willing to attribute my own failure to have previously encountered such a case in a child in part to faulty bronchoscopic interpretation. It has been intriguing to my colleagues and myself, after my first experience, that in such a short period we have been able to diagnose 15 cases and in eight of these to have found caseous masses containing tubercle bacilli penetrating a bronchus. Dr. Myerson mentioned the greater reluctance of bronchoscopists in the United States to subject children to bronchoscopic examinations. That may be so, but I feel that a child manifesting signs of possible foreign-body aspiration, such as wheezing—as some tuberculous children do—or x-ray evidence of atelectasis or emphysema is entitled to treatment both from diagnostic and therapeutic standpoints. Regarding the question of thiopental sodium anesthesia, anesthetists with whom I associate feel it is contraindicated in children. In our hands ether has proved to be a safe anesthetic in these cases. I agree regarding the preponderance of bronchial ulcerations found at postmortem as compared with those seen bronchoscopically during life. This is particularly true of the adult type. We, fortunately, have had no fatalities in our children to permit comparison. As to the question of other types of edema not directly associated with tuberculous invasion that may be found in bronchi of tuberculous individuals, I, too, have seen these in adults having received artificial pneumothorax, etc. However, since these children had not had collapse therapy this question did not arise. A child's bronchus that has been encroached on by tuberculous nodes presents the picture of a lumen that has been narrowed by external compression. When the nodes have penetrated the bronchial wall the caseating material and the adjacent ulcerogranulomatous masses are unmistakable.

HYPERTROPHIC OSTEOARTHROPATHY IN CARCINOMA OF THE LUNG

John D. Pattison Jr., M.D., Toledo, O., Erwin Beck, M.D.
and
William B. Miller, M.D., Pittsburgh

Hypertrophic pulmonary osteoarthropathy, or hypertrophic osteoarthropathy, received its name from Pierre Marie in 1890, but was first described by Eugen Bamberger in 1889. As defined by Marie in 1890, it is a "symmetrical osteitis of the four limbs, chiefly localized to the phalanges and terminal epiphyses of the long bones of the forearm and leg, sometimes extending to the roots of the limb and flat bones, and accompanied by a dorsal kyphosis and some affection of the joints." This definition clearly differentiates hypertrophic osteoarthropathy from simple clubbing of the fingers and toes. Clubbing is a proliferative change of the soft tissues about the terminal phalanges with no constant osseous changes. It is believed by some [1] to be the early stage of hypertrophic osteoarthropathy.

Hypertrophic osteoarthropathy, with rare exception,[2] is secondary to an acute or chronic affection of the viscera. It is occasionally associated with conditions outside of the thoracic or abdominal cavities. It has been reported following subtotal thyroidectomy,[3] in carcinoma of the nasopharynx,[4] in carcinoma of the thymus,[5] in benign tumors of the chest wall including fibromas and lipomas [6] and in myelogenous leukemia.[7] The visceral lesion is usually pulmonary, comprising bronchiectasis, abscess, empyema, tuberculosis, pneumonia,[8] or neoplasm, but may be cardiac, hepatic, or gastrointestinal, such as congenital heart disease with cyanosis, subacute bacterial endocarditis, biliary cirrhosis,[9] colitis,[10] rectal strictures, chronic pyloric obstruction, and sprue.[7]

It is the purpose of this paper to emphasize the occurrence of hypertrophic osteoarthropathy in neoplastic disease of the chest, particularly bronchogenic carcinoma, in which it may produce the earliest symptoms, which are numerous. They most commonly consist of aching pains and tenderness in the joints and along the shafts of the long bones, transient increase in joint fluid usually not associated with local inflammatory signs, muscular weakness, edema and hypertrophy of the subcutaneous tissues of the extremities, burning sensations and increased sweating of the hands and feet, gynecomastia, and other evidence of endocrine imbalance. Because of the similarity of most of the above symptoms to those of rheumatic disease, many cases of bronchogenic carcinoma have been treated for many months as rheumatoid arthritis before a chest x-ray revealed the underlying pathology. The one important feature of this condition in its relation to pulmonary neoplasm is that it usually precedes the pulmonary symptoms by a period of time sufficient to allow successful surgical removal of the malignant lesion. This is in rather marked contrast with chronic suppurative conditions of the chest in which the diagnosis is made long before the appearance of hypertrophic osteoarthropathy. In the past, this condition has been associated more commonly with suppurative than with neoplastic disease of the chest. It is important for us to appreciate its not infrequent occurrence in carcinoma of the lung as a clue to earlier diagnosis.

Brooks [11] reviewed 57 cases of hypertrophic osteoarthropathy reported up to 1913; of these, six had primary pulmonary neoplasm, seven had malignant mediastinal tumors and one had no known primary lesion. In 1915 Locke,[9] in his review of 139 previously reported cases and five of his own, found bony changes associated

with pulmonary or mediastinal malignancy in nine, one having had symptoms of hypertrophic osteoarthropathy for five years before a primary lung neoplasm was found. Craig[12] reported four cases of bronchogenic carcinoma with emphasis on the fact that in each case the earliest symptoms were due to hypertrophic osteoarthropathy; three had been diagnosed as rheumatoid arthritis and one was diagnosed as acromegaly. In all four cases, bone symptoms preceded the pulmonary symptoms from eight to 11 months. In a recently reported case[13] of adenocarcinoma of the lung, clubbing and bone symptoms appeared one and one-half years before chest symptoms. A feature of this case was gynecomastia, which was also present in one of our cases and one of Fried's.[14] Duncan,[15] Ayre[16] and Poppe[17] have all stressed the significance of clubbed fingers, and especially of osteoarthropathy, as a valuable early sign in pulmonary neoplasm.

In the widely varied diseases that have been found to produce hypertrophic osteoarthropathy, no common denominator is evident as a basis for its pathogenesis. The similarity to acromegaly has long been noted, and, because of the spadelike enlargement of the hands and feet, this is a frequent early misdiagnosis. Fried[14] described four cases of bronchogenic carcinoma with severe osteoarthropathy, which strongly suggested pituitary dysfunction as an important contributing factor; at necropsy, three had definite hyperplasia of the eosinophilic cells of the anterior lobe of the pituitary. In our second case, there were acromegalic changes, but careful histological examination of the pituitary showed only a miniature basophilic adenoma.

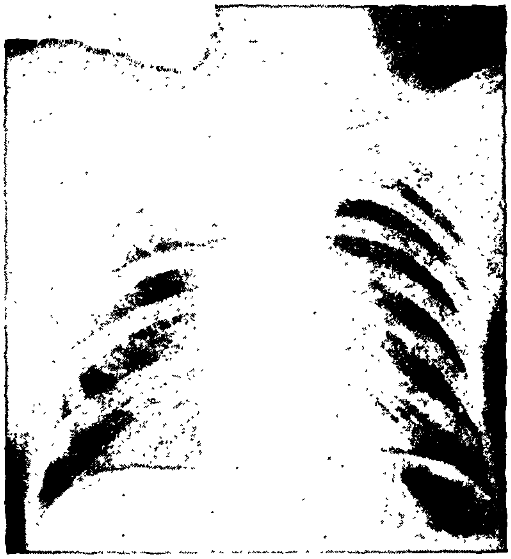

Fig. 1 (case 1).—Homogeneous density in right upper lobe proved by aspiration biopsy to be caused by bronchogenic carcinoma, which could not be classified.

Mauer's[18] speculations as to the pathogenesis of clubbing and secondary osteoarthropathy, based upon actually observed phenomena, suggest many possible contributing factors. In all of the diseases that may cause secondary soft tissue and bony changes, there is usually an elevated erythrocyte sedimentation rate, which results from an increased blood fibrinogen and globulin content and leads to increased rouleaux formation, reduced surface area of the erythrocytes, and impaired oxygen release to the tissues. Charr and Swenson[19] have demonstrated by infrared photographs of living persons and post-mortem arteriograms that the local vascular bed is increased and widened in cases of clubbing. This means that there is an increased peripheral blood flow. The increased peripheral blood flow plus the reluctance of the erythrocytes to release their oxygen leads to arteriolar anoxia, low-tissue oxygen tension, and clubbing.

The gross pathology of bones in hypertrophic osteoarthropathy consists of irregular, porous, rough accumulations of newly formed periosteal bone, which is usually thickest in the region of the peripheral epiphysis and is more pronounced at the lines and points of musculotendinous insertions. Microscopically, the periosteum may be thickened and may contain increased accumulations of lymphocytes and round cells. There may also be small hemorrhagic areas and areas of edema and vasodilatation not unlike those seen in local osteophyte formation. The cortex of the old bone becomes eroded, and occasionally bone metastases from malignant pulmonary neoplasms will be seen in the bones affected by hypertrophic osteoarthropathy. The marrow of both the newformed periosteal bone and of the old bone is richer and more vascular in the areas of active periosteal proliferation and fattier in the inactive areas. The synovial membranes may present fibroid degeneration, subsynovial congestion and collections of lymphocytes and leukocytes with eventual proliferation of granulation tissue and pannus formation. Pannus pressure may cause degeneration of the cartilage.[10]

Although the soft tissue and bony changes that constitute this clinical entity are usually so marked and show such definite pathological changes, they are reversible and will disappear entirely if the primary condition is cured.[20] The symptoms and objective findings may improve or disappear with dramatic speed once the primary lesion has been treated (cases 5 and 6), surgically or by x-ray therapy.[21]

REPORT OF CASES

Case 1.—L. L. E., a white man aged 52, first noted pain and swelling of his hands and feet eight months before hospital admission. His knees, hips, shoulders, elbows, wrists, and fingers soon became similarly involved, and three months before admission his breasts became hard and painful. His feet and hands became progressively larger, and he lost 25 lb. (11 kg.) in weight in spite of a good appetite. There were no significant symptoms referable to his chest. On admission his fingers and toes were clubbed; the feet, ankles, knees, fingers, hands, and wrists were swollen, enlarged, warm, and painful to touch. All joint movements were painful. A tentative diagnosis of acromegaly was suggested.

The blood cell count, the results of the serologic study, and the blood calcium, phosphorus, and alkaline phosphatase were normal. The sedimentation rate was very rapid and the basal metabolic rate was plus 23%. A chest film showed a homogenous density in the upper third of the right lung field (fig. 1), and x-rays of the extremities showed subperiosteal new bone formation in the metacarpals, phalanges, femora, tibiae, and fibulae; several joints showed irregularity and demineralization suggesting rheumatoid arthritis; the sella turcica appeared normal. Biopsy of an axillary node was noncontributory, but an aspiration biopsy of the right lung (done at the Veterans Administration Hospital, Bronx, N. Y.) showed carcinoma, which could not be classified. Roentgen therapy gave temporary palliation, but later chest roentgenograms showed progression of the lung lesion with rib destruction. The patient died 10 mo. after admission.

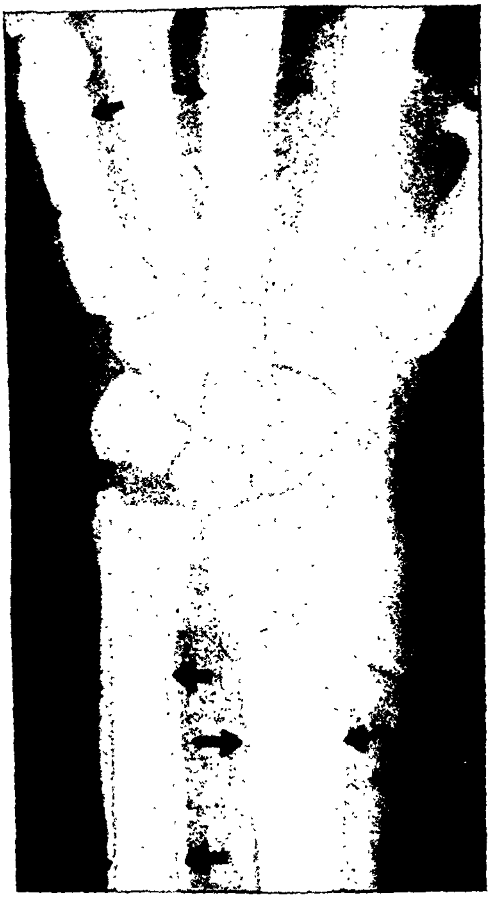

Fig. 2 (case 2).—Reactive periositis (hypertrophic osteoarthropathy) of the radius, ulna, and metacarpals in bronchogenic carcinoma.

Comment.—Symptoms of hypertrophic osteoarthropathy and clubbing appeared eight months before a primary lung carcinoma was found. There was a rapid sedimentation rate and gynecomastia, the latter suggesting endocrine dysfunction.

Case 2.—L. J. D., a white man, aged 52, was sent to the hospital on April 18, 1947, with a diagnosis of multiple acute arthritis. The pain and swelling of his ankles and wrists, of three months' duration, had failed to respond to therapy. There were *no symptoms referable to his chest and all other symptoms* were noncontributory except for some weight loss. His hands, fingers, and toes were tender and had increased in size, requiring him to have his wedding ring enlarged from a size 10 to a size 13. There was no clubbing of the fingers and his joints were not painful on movement. Later increased joint fluid developed in both knees. His entire hospital course was febrile with temperatures ranging from 99 to 103 F. Roentgenograms of the extremities showed marked, serrated, irregular, reactive periostitis of the femora, tibiae, fibulae, ulnae, radii, metacarpals (fig. 2), and the lateral portion of both clavicles; the distal phalanges were *normal*.

A chest x-ray (fig. 3) showed increased, beaded, linear markings extending upward from the left hilus to the apex, suggesting an old tuberculous process. The sella turcica was slightly enlarged in its anteroposterior diameter (15 mm.), but was otherwise normal. An admission blood cell count, serologic study, and blood calcium, phosphorus, and alkaline phosphatase were all normal. The sedimentation rate was 32 mm. in an hour.

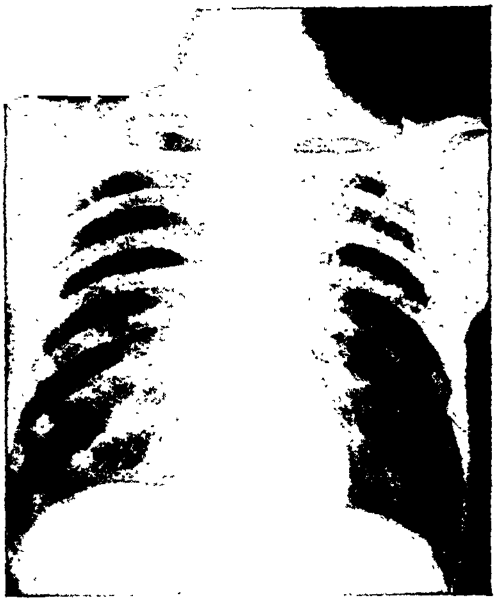

Fig. 3 (case 2).—Bronchogenic carcinoma (grade III) in left upper lobe, the roentgenologic appearance of which suggests tuberculosis rather than neoplasm.

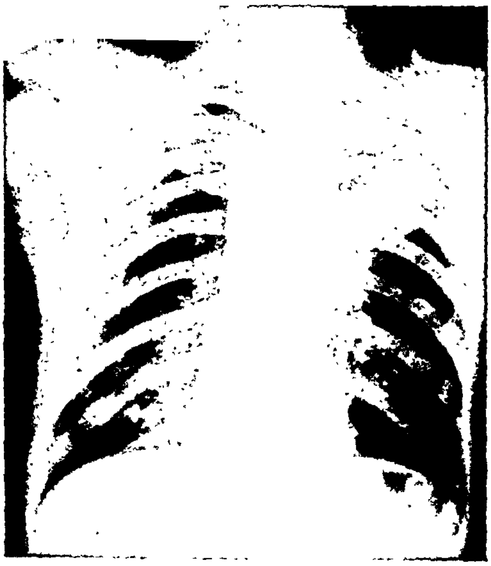

Fig. 4 (case 3).—Bronchogenic carcinoma, left upper lobe.

Four weeks after admission, three nodes were noted in the left supraclavicular area and a biopsy of these nodes showed metastatic squamous cell carcinoma, grade III. His general condition rapidly became worse, and he died about five weeks after admission.

Necropsy.—The upper lobe of the left lung and its pleural surface were studded with tumor nodules. The nodes extending from the left main bronchus to the homolateral cervical region were enlarged and filled with tumor cells. A secondary branch of the left upper lobe bronchus contained an infiltrating tumor mass 1 cm. in diameter. Retroperitoneal nodes were also found to contain tumor cells. Histologic diagnosis was bronchogenic carcinoma, grade III. A section from the tibia showed the typical pathological appearance of hypertrophic osteoarthropathy. The pituitary was normal in size but contained a miniature basophilic adenoma, probably of no clinical significance.

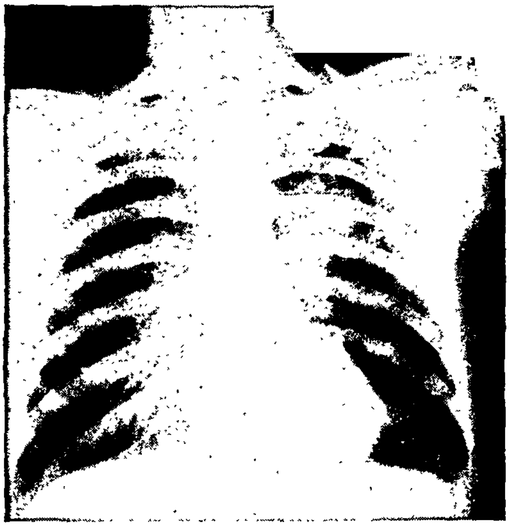

Fig. 5 (case 4).—Bronchogenic adenocarcinoma, left upper lobe.

Comment.—Symptoms of hypertrophic osteoarthropathy preceded the chest symptoms by three months, and the provisional diagnosis was multiple arthritis. The patient had spadelike enlargement of the hands, suggesting acromegaly, and an elevated sedimentation rate. The original chest x-ray was not diagnostic of carcinoma; clubbing of the fingers was not present; the pituitary was not significantly abnormal.

Case 3.—J. P. A., a white man aged 51, had had a questionably productive cough for three years but was otherwise well until three months before admission, when he began to have swelling and pain in both legs and ankles. Eight weeks before admission he developed blurred vision, severe frontal headaches, and disturbed sensorium. He became slightly confused and his speech thickened at times. He was admitted to the Veterans Administration Hospital, Aspinwall, Pa., with a diagnosis of left frontal lobe tumor.

On admission he had bilateral papilledema with retinal hemorrhages, disturbed sensorium, and abnormal physical findings in the apex of the left lung. There was marked clubbing of the fingers and toes and tenderness to pressure over the distal ends of the tibiae. Blood cell count and blood chemistry values including calcium were normal. The sedimentation rate was 23 mm. in one hour. Bronchoscopy failed to visualize a lesion after a roentgenogram of the chest (fig. 4) had shown an area of increased density extending from the left hilus to the left lateral chest wall and suggestive of atelectasis. X-rays of the extremities showed faint, periosteal new bone formation involving the tibiae, fibulae and radii. A diagnosis of bronchogenic carcinoma with cerebral metastasis and hypertrophic osteoarthropathy was made. His condition deteriorated rapidly and he died one and a half months after admission.

Necropsy.—The clinical diagnosis was confirmed, and, in addition, metastatic lesions were found in the pleura, pericardium, kidneys, and regional lymph nodes.

Comment.—This case showed marked clubbing, but minimal periosteal reaction or proliferation. As in the previous cases, symptoms of hypertrophic osteoarthropathy preceded significant pulmonary symptoms.

Case 4.—F. B., a white coal miner, aged 58, was hospitalized because of dyspnea of many years duration, which had become worse in the previous three months, swelling and aching of ankles, hands, and elbows of three months' duration, and precordial pain radiating down the left arm, of five years' duration. Other complaints on admission were a chronic cough for years without hemoptysis, but with occasional mucopurulent sputum, and a 15 lb. (6.8 kg.) weight loss in the previous two weeks. Physical examination on admission was essentially noncontributory except for the extremities, which showed clubbing of the fingers and toes, moderate bone tenderness and swelling of the hands, elbows, feet and ankles. A chest x-ray (fig. 5) showed a well-demarcated area of increased density at the level of the second left interspace anteriorly measuring 5.5 cm. in diameter. X-rays of the extremities showed periosteal proliferation along the radii, ulnae, tibiae and fibulae. Blood cell count and blood chemistry, including content of sugar, nonprotein nitrogen, cholesterol and uric acid, were normal. The sedimentation rate was slightly elevated—23 mm. per hour. Tests on sputum were negative for tubercle bacillus. The interpretation of an electrocardiogram was consistent with an anterior myocardial infarct. Bronchial secretions were negative by the Papanicolaou method, but an aspiration biopsy was positive for undifferentiated carcinoma. High-voltage roentgen therapy was instituted because it was felt that the patient was inoperable. Death ensued three months after admission.

Necropsy.—The autopsy revealed bronchogenic adenocarcinoma of the left lung with metastatic lesions in the adrenals and the pleura.

Comment.—The symptoms of hypertrophic osteoarthropathy present in this case were somewhat overshadowed by other complaints; nevertheless, they occurred comparatively early in the course of the disease.

Case 5.—R. R. S., a white man, aged 48, was admitted to the hospital because of swelling and aching of his knees, ankles, elbows, and wrists, of eight weeks' duration, associated with loss of appetite, weight, and strength. A local doctor diagnosed his condition as arthritis. Weakness and pain in the extremities progressed to the point where he was forced to quit his job. He had profuse night sweats shortly before admission. His only respiratory symptom was a chronic "cigarette cough." A chest x-ray 20 mo. prior to admission was negative. On physical examination he appeared chronically ill; his knees seemed slightly thickened; his ankles showed moderate nonpitting edema; and

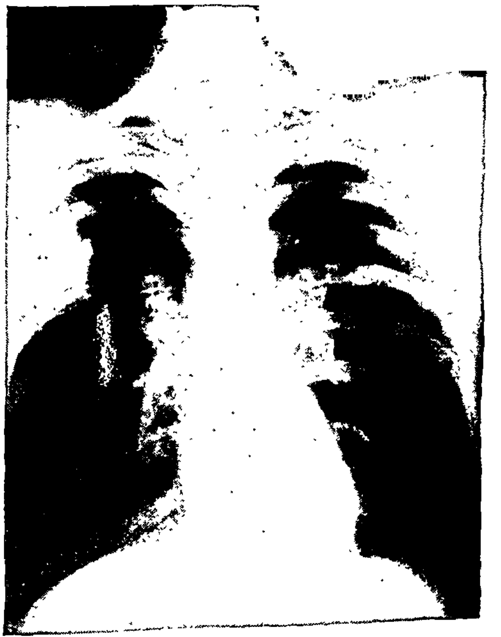

Fig. 6 (case 5).—Peripheral adenocarcinoma of the right upper lobe.

bone tenderness was present in the distal portions of the tibiae. The initial clinical diagnosis was rheumatoid arthritis.

X-rays of the extremties showed periosteal reaction of the distal ends of the femora, tibiae, and fibulae. A chest x-ray (fig. 6) showed a well circumscribed, peripheral, homogeneous density 5.5 cm. in diameter at the level of the third right anterior rib. There was a moderate anemia; the sedimentation rate was moderately elevated—28 mm. per hour; blood sugar and nonprotein nitrogen were normal; the serologic study was negative. Clubbing of the fingers and toes was noted. Bronchoscopy revealed no abnormality, and bronchial secretions showed no malignant cells. Right pneumonectomy was performed, showing no evidence of metastatic involvement in the thorax. Within 24 hr. after the operation, pain and tenderness of the legs had already subsided. Death on the fourth postoperative day was attributed to shock and pulmonary edema.

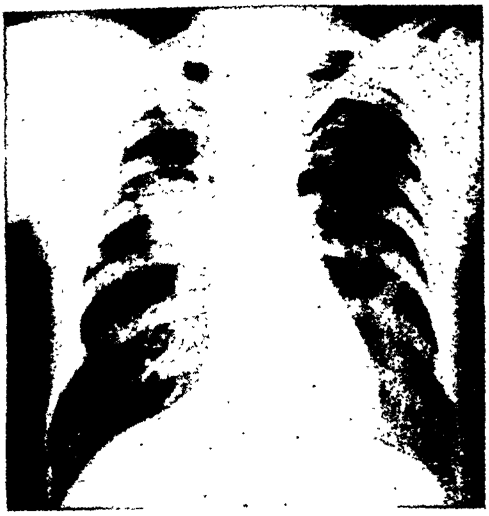

Fig. 7 (case 6).—Bronchogenic adenocarcinoma at the base of the right upper lobe anteriorly, discovered on routine chest x-ray.

Microscopic examination revealed a peripheral adenocarcinoma of the right upper lobe.

Comment.—This case shows the occurrence of the symptoms of hypertrophic osteoarthropathy at least two months before a pulmonary neoplasm was found. These symptoms responded dramatically to the removal of the primary lesion. Another interesting note in this case is that this man was refused hospitalization two months previous to his admission because it was felt that he had rheumatoid arthritis and that hospitalization was not urgent.

Case 6.[21]—F. W. O., a white man, aged 60, sought medical attention because of pain and swelling of his legs. The pain and swelling were first noted about two months before he went to his family doctor, and they gradually became worse. A complete systemic review was noncontributory except for some slight exertional dyspnea, which had existed for many months. His past medical history consisted of the usual childhood diseases and a bleeding peptic ulcer 14 years previously. Positive physical findings were confined to the extremities. On both forearms there were multiple, small, soft, freely moveable subcutaneous nodules, not unlike lipomas. Both feet and ankles were swollen, the skin seemed slightly thickened, and there was a three plus edema of both legs. The knees later became swollen and ached constantly. The peripheral vessels were moderately sclerosed.

A routine chest roentgenogram (fig. 7) revealed a well-circumscribed, homogeneous density occupying the base of the right upper lobe anteriorly. Because of this chest finding, he was hospitalized for diagnostic study and observation. The original blood cell count showed a moderate anemia. Urinalysis and results of serologic examination were noncontributory. The total protein value was 5.9 gm. per 100 cc. with an albumin value of 3.94 and a globulin value of 1.96. Gastrointestinal study showed a deformed duodenal cap, and x-rays of his extremities showed minimal osteoarthritic changes in the ankle, minimal calcification of the large vessels of his legs, and periosteal reaction of the tibiae, fibulae, and femora. Bronchoscopy showed an edematous, granular orifice to the right upper lobe bronchus, but biopsy and Papanicolaou study of bronchial secretions were negative.

During the two-week period of preoperative study there was no essential change in the patient's complaints, physical findings, or the pulmonary lesion. A right pneumonectomy was performed and the pathological diagnosis was adenocarcinoma of the lung. At the time of surgery no evidence of metastasis could be found. Approximately 15 hr. after surgery, all subjective symptoms with reference to his extremities had disappeared, the edema was much less, and bone tenderness was no longer present.

Comment.—This was another case of bronchogenic carcinoma, in which the symptoms of hypertrophic osteoarthropathy preceded any evidence of chest pathology by more than two months and led to the correct diagnosis.

SUMMARY

Six cases of bronchogenic carcinoma with associated hypertrophic osteoarthropathy are reported. In five of them the symptoms of hypertrophic osteoarthropathy were the first significant symptoms, constituting a valuable early diagnostic finding in carcinoma of the lung.

Some aspects of the pathogenesis of hypertrophic osteoarthropathy are reviewed.

The occurrence of hypertrophic osteoarthropathy in neoplastic disease of the lungs is emphasized.

ADDENDUM

Since acceptance of this paper for publication, two additional cases have been observed. The first patient was admitted for "active, multiple rheumatoid arthritis" of six months' duration, with no chest symptoms. Routine chest roentgenogram showed three well-defined, right lower pulmonary densities. Histological proof of primary or secondary neoplasm was lacking, and autopsy was not permitted. Advanced hypertrophic osteoarthropathy was present.

In the second case, no significant symptoms related to the hypertrophic osteoarthropathy were present, chest symptoms being predominant. Histological proof of pulmonary neoplasm was still lacking at the time of pneumonectomy for adenocarcinoma, grade III, although hypertrophic osteoarthropathy had been demonstrated roentgenographically five weeks previously.

[21] This was Dr. Monroe Cronstine's patient (Toledo, Ohio) and was seen in consultation by one of us (J D.P.).

A Single Case Report by Opie.—Of the numerous ways in which pathological studies have contributed to the understanding of disease, an important one is found in the suggestions for the direction of experimental work that have derived from studies of human material. An illustration is the impetus of clinical investigation that came from a single case report by Opie. This report described hyalinization of the islands of Langerhans in a patient dying of diabetes mellitus and suggested an etiologic relation. Although it soon became apparent that the lesion is not constantly present in diabetic patients, the paper focused attention on the role of the islands of Langerhans in diabetes and pointed the way to further investigations that have greatly increased the available knowledge of the physiology and therapy of the disease. HYPERVITAMINOSIS A

REPORT OF A CASE IN AN ADULT

Marion B. Sulzberger, M.D.
and
M. Paul Lazar, M.D., New York

The paucity of published reports of hypervitaminosis A indicates the relatively low incidence of this syndrome. However, the increasing number of publications about the symptom complex since Josephs'[1] article in 1944 suggests that many cases of clinical hypervitaminosis A may have been overlooked in the past. Prompted by new findings, leading medical journals on each side of the Atlantic Ocean recently have had editorials on the subject.[2]

In addition to Josephs' description, Toomey and Morissette,[3] Rothman and Leon,[4] Fried and Grand,[5] Dickey and Bradley,[6] Wyatt, Carabello and Fletcher[7] and Caffey[8] have presented additional material concerning the now well established syndrome of hypervitaminosis A in man. Furthermore, experiments on laboratory animals given large doses of vitamin A have not only helped to delineate the clinical signs but, of greater importance, have provided material for the study of physiological, chemical and histological changes induced by overdosage with this generally comparatively innocuous substance.[9]

As far as we have been able to ascertain, at the time of this publication all the cases presented (eight reported in full and casual reference to eight others) have occurred in young children. Our patient was an adult whose physiological, chemical and general body economy would obviously differ from that of a child or infant. As described below, despite this distinct age differential, the general syndrome in our patient was basically similar to that previously reported in infants and children.

REPORT OF CASE

Mrs. N. R., a 44 year old white woman,[10] was first seen by us on May 25, 1950. While she consulted us chiefly because of excessive loss of hair, it developed that during the preceding six months the patient had been experiencing various difficulties, which included the following: (1) For five months prior to our seeing the patient, her menstrual cycle, though regular, was three days shorter than previously. The flow lasted five days instead of eight and was less than usual. A thorough examination by her gynecologist revealed no abnormalities. (2) Generalized joint and bone pains, migratory in nature, were first present in March 1950. These were treated by thiamine and penicillin injections with equivocal results. The severity of the pains fluctuated a great deal so that at times they would disappear spontaneously; though the discomfort was great, at no time was it necessary for ordinary household duties to be put aside. (3) Examinations performed because of the pains led to the discovery and extraction of two infected teeth. These extractions, performed in March 1950, did not check the joint and bone pains. (4) Soreness and fissuring appeared in January 1950 at the corners of the mouth and the nasal apertures. These also were treated with a series of thiamine injections; there was no apparent improvement. (5) Skin changes which dominated the complaints included generalized pruritus, a dry, rough skin with a widespread branny desquamation and excessive loss of hair beginning in the last two months with thinning of scalp hair and loss of the eyebrows, eyelashes, axillary and pubic hairs and lanugo hairs. (6) She experienced night sweats during the last six months. (7) According to the patient, her eyes were more prominent than they had been previously.

Family History.—The patient's family history was noncontributory. There was no history of skin disease, abnormalities of hair or nails, atopy or other familial disease.

Personal History.—At age 6, the patient had an "eczema" between her fingers. In 1941 an amputation of the cervix was done, and in 1947 the patient had virus pneumonia. Otherwise, the patient has always been a generally healthy person.

Physical Examination.—Abnormal findings included tenderness over various long bones, the spine and the large joints which could be elicited by deep pressure. A slight bilateral exophthalmos was observed which the patient stated had been present for several months; but one must view this observation as being of doubtful significance, for we had not seen the patient prior to the onset of the syndrome. All the other abnormal findings were limited to the skin and its appendages.

The skin was generally warm and dry. The hairs of the scalp, axillary and pubic areas were coarse, brittle, dry and easily pulled from their moorings. Those comprising the eyebrows and eyelashes were almost entirely gone, and no lanugo hairs could be found anywhere on the body. The scalp hair present was difficult to manage and appeared unkempt. A chloasma-like or Riehl's melanosis-like pigmentation was present on each side of the face and neck. A pruritic, excoriated, superficial and finely scaling dermatosis was present over the upper back and all the extremities. Distinct, elevated, minute follicular papules and follicular hyperkeratoses were evident on the extremities and, in particular, on the thighs and lateral surfaces of the arms. Slight scaliness and superficial fissuring were present at the nasal apertures and corners of the mouth. Papular acneform and milia-like lesions were present on the face, particularly on the forehead. The finger nails were soft and brittle, and onychorrhexis was present.

Further questioning at this time revealed that the patient had been taking about 600,000 units of vitamin A daily during the 18 month period prior to our seeing her. This self medication was inspired by a radio "nutrition commentator" who suggested that vitamin A was good for "alleviating dry throats and as a prophylactic for colds." Our patient grasped this cue and, in her zeal, established a daily 600,000 unit dose (supplemented by doses of 1,000,000 units to 2,000,000 units on special occasions, e. g.,

[10] Dr. Jacob Cohen of Brooklyn referred the patient to us.

suspicion of oncoming colds or dry throat). The vitamin preparation employed was supplied in 50,000 unit capsules by a large local pharmacy and contained no vitamin D. The patient's husband somehow began to suspect that this vitamin might be harmful, and the medication was stopped voluntarily on May 20, 1950, five days before we saw the patient for the first time.

Several urinalyses gave results which were normal in every respect, including that for calcium excretion. Basal metabolic rates determined on two occasions one week before we saw the patient were + 7 and 0; two determined six years ago were — 9 and — 4. Roentgenograms of several long bones and joints were made June 1, 1950 and showed only normal features. Those areas tender on deep pressure were selected for radiography. A scout film of the abdomen revealed no abnormalities such as renal calculi or metastatic calcification.

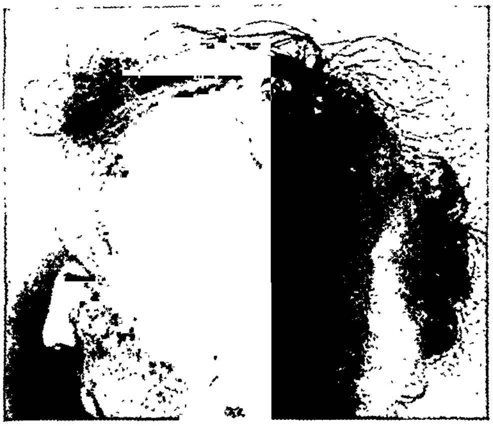

Fig. 1.—Photograph taken June 1, 1950. Note sparseness of scalp hair and unkempt appearance. The scalp may be seen easily through the hair. (Vitamin A self medication started about Dec. 1, 1948 and stopped on May 20, 1950.)

Therapy and Course.—The only therapy advised was that of continued avoidance of the supplementary vitamin A intake, the patient having ceased to take the vitamin five days before seeing us. Those foods containing large amounts of vitamin A were restricted as much as possible. Though vowing to cooperate, the patient was reluctant to believe that anything as beneficial as a vitamin could actually have caused such difficulties.

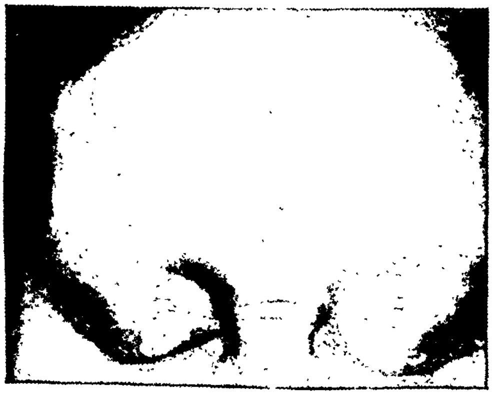

Fig. 2.—Photograph taken June 1, 1950. Note loss of eyebrows and eyelashes. Small milia-like lesions may be seen just above the glabella. Chloasma-like pigmentation is apparent on the lateral aspects of the forehead.

Within 10 days after the patient stopped taking the vitamin A, the joint and bone pains disappeared, as did the pruritus and superficial branny desquamation of the skin. The patient now was convinced of the role of the vitamin in the syndrome. The follicular hyperkeratoses on the extremities and fissuring at the corners of the mouth and nose were gone several days later. Because of the rapidity of involution of these particular lesions, we unfortunately missed the opportunity of getting photographs of them. However, the following photographs, taken on June 1, 1950 (figs. 1, 2 and 3), give various views of the remainder of the syndrome, as evidenced by the pigmentary, hair and skin abnormalities seen on the head; and the photographs, taken on Sept. 26, 1950 (figs. 4, 5 and 6), show the evolution of these changes during the approximately four month abstinence from vitamin A medication.

As the latter half of June approached (four weeks after the cessation of additional vitamin A consumption), new, fine and coarse hairs began to appear in all areas where previously they had been lost. However, the finger nails continued to become worse, and it was only at the end of July (10 weeks after the vitamin A capsules had been discarded) that they began to show a tendency to revert toward normal. Though the dystrophy and recovery of the nails did lag behind that of the other epidermal appendages, when seen in September (about four months after the original visit) the patient was normal except for the shortness of the hair and the residual chloasma-like pigmentation (figs. 4, 5 and 6).

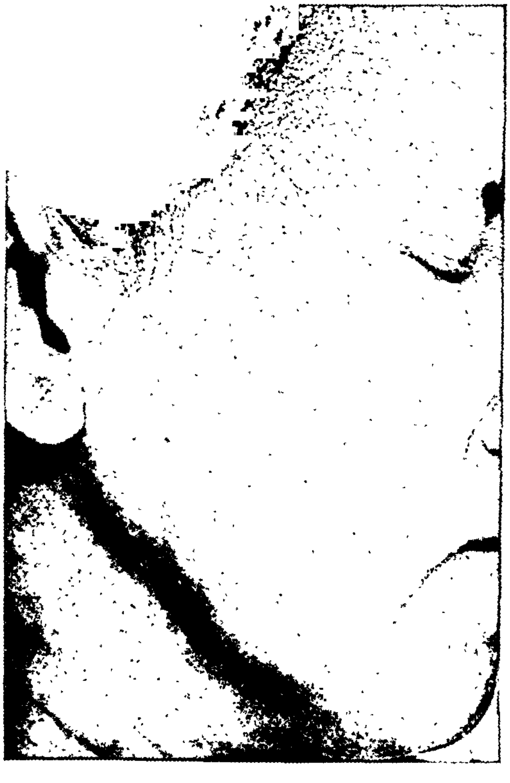

Fig. 3.—Photograph taken June 1, 1950. Chloasma-like pigmentation is easily seen, as is the lack of eyebrows, eyelashes and facial hair. Milia-like lesions are present on the cheek

The night sweats disappeared, and sweating was reported to be normal throughout the summer.

The hair gradually became more manageable, and its fall became minimal by mid July. The menstrual cycle returned to what it had been one year previously and to the normal intervals which had always existed prior to that time. Little or no change occurred in the slight exophthalmos. At no time did the patient experience difficulty with her eyesight, though she did claim that her eyelids had a "granular feeling" shortly before she came to the office.

COMMENT

Although the picture of hypervitaminosis A is not yet generally well known to clinicians, there are sufficient reports and experimental data for one to consider it a well established and characteristic syndrome. Its inclusion for the first time in standard American medical textbooks [11] will doubtless lead to a more general recognition of this symptom complex by the practitioner.

As far as we have been able to discover, up to the present all articles on the undesirable effects of excessive amounts of vitamin A have dealt with the syndrome as occurring in very young children and laboratory animals. To the best of our knowledge the present report is the first to record observations of hypervitaminosis A in the adult human being. The findings closely follow the pattern already established in children and experimental animals, but several deviations from and additions to the accepted syndrome were present in this case.

Menses.—As all the previously reported cases occurred in infants, the menstrual changes in our patient automatically introduce another and new aspect of prolonged vitamin A overdosage. One cannot rule out the possibility that the menstrual changes in our patient may have been a spontaneous or physiological alteration since the patient was in the age group of those often undergoing menopausal changes. Nevertheless, the onset of the menstrual disturbances at the time of the other disturbances and the reversion to normal menses when the vitamin A medication was stopped speak strongly in favor of the assumption that the alterations in menstruation were actually a part of the hypervitaminosis A syndrome. If this assumption is correct, then either endocrine imbalance or disturbances in bleeding or coagulation might, one or both, underlie the menstrual aberrations; the few studies done on our patient shed no light on the cause of the menstrual changes.

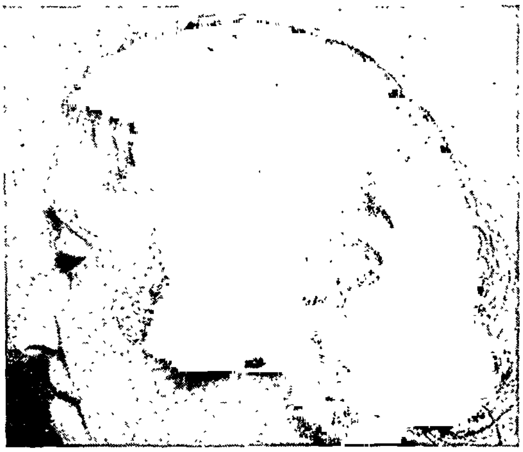

Fig. 4.—Photograph taken Sept. 26, 1950. Note regrowth and orderly appearance of the scalp hair. Short hairs extend over the upper part of the forehead. Note the return of the facial, eyelash and eyebrow hair.

In this connection it is noteworthy that in other cases of hypervitaminosis A, hypoprothrombinemia, correctable by vitamin K administration, has been shown to be the basis for hemorrhages (for example, such as that which followed tonsillectomy in Josephs' patient [1]). Severe hemorrhage and even death have occurred spontaneously and after minor trauma in animals with hypervitaminosis.[12] Therefore, in any suspected or proved case of hypervitaminosis A, caution should be exercised in regard to interferences that might cause bleeding. Even minor surgical procedures may precipitate severe hemorrhage—though this fortunately did not occur after dental extractions in our patient.

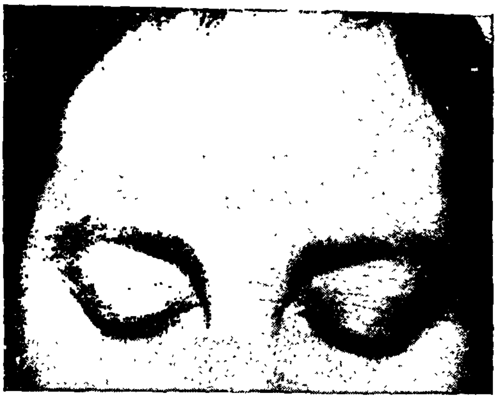

Fig. 5.—Photograph taken Sept. 26, 1950. Note excellent hair regrowth in eyebrow and eyelash areas, as well as on the face. Chloasma-like pigmentation may still be seen on the forehead. Milia-like lesions are gone.

Although the mechanism of vitamin A hypoprothrombinemia is unknown, it appears possible that the excess of vitamin A may perhaps interfere with the synthesis of vitamin K by the intestinal flora, or it may disturb absorption or increase the need for vitamin K, or it may destroy or inactivate vitamin K in the liver or elsewhere in the body.

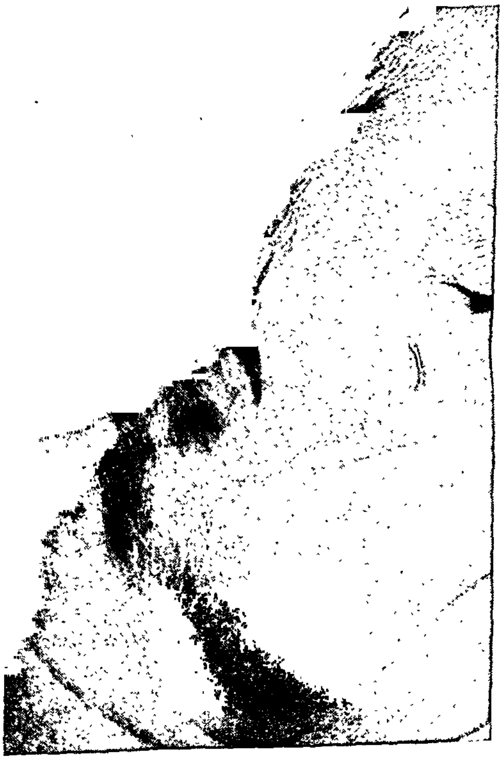

Fig. 6.—Photograph taken Sept. 26, 1950. Note extensive hair growth on the face and regrowth in the eyebrow and eyelash areas. The chloasma-like pigmentation, though lighter, is still visible. Milia-like lesions on the cheek are gone.

The fractures observed in the animal with vitamin A toxicosis are not prevented by vitamin K which, however, corrects the ever present hypoprothrombinemia. These two manifestations may also be isolated from one another by the administration of bishydroxycoumarin (dicumarol®) which causes hemorrhage but not fractures.[13]

Pigmentation.—Not heretofore described as a component of this syndrome was the chloasma or Riehl's melanosis-like pigmentation present in our patient. Again, one could speculate about the appearance of this pigmentation being a coincidence instead of a result of the excessive vitamin A intake. Yet its concomitant appearance with the other well established signs and symptoms and its fading on withdrawal of the vitamin A (though during this three month period the patient was exposed regularly to the summer sun) lead us to incline to the opinion that this is a newly observed component of hypervitaminosis A. Our meager understanding of the basic physiological mechanisms underlying the appearance of chloasma or Riehl's melanosis makes it impossible for us to explain this phenomenon.

Skeletal System.—Apparently the mature structure of bone is not so labile as a child's in its response to outside influences. This could well explain why the roentgenologic features regularly and characteristically found in children were missing in our adult case. Wolbach and others make the following statement in connection with their extensive studies in laboratory animals: "It should be kept in mind that the results on bone of excessive vitamin A administration are exhibited only in the growing animal and only in regions undergoing growth." [9a] Moore and Wang noted the same findings and wrote: "In adult rats, the bones are probably more resistant to fractures, since we detected no breakages in our older animals." [9d]

Itching.—Generalized pruritus is another feature which has been a constant component of the syndrome. Infants and animals fed excessive doses of vitamin A have regularly shown the presence of itching. Generalized moderately severe itching was also a prominent symptom in our patient. The questions of the origin and mechanism of this pruritus are still unsolved.

Is the pruritus due to primary epidermal changes? Could the threshold be lowered locally by the faulty keratinization and dryness of the skin? This would be the simplest and, therefore, the first hypothesis for investigation. However, hypervitaminosis A produces many other complex systemic and internal changes which can lead to itching. These include alterations in the delicate balance and interplay between the liver and the nervous, cardiovascular and endocrine systems; local and general alterations in physical and chemical balance, as exemplified by the ratio of anions, cations and colloidal particles; changes in pH and surface tension, disturbances in enzyme systems—all or any of these may directly or indirectly influence both peripheral and central prurigenic irritability. All these factors must, therefore, be considered in the further study of this complex problem.

Keratin Structures.—To dermatologists and to all other students of this syndrome, extraordinary interest must attach to the changes found in the horny structures, the hair, finger nails and horny layers of the skin. In our case also, all these structures were disturbed by the inordinate consumption of vitamin A and in a manner remarkably reminiscent of hypovitaminosis A.[14] Previous reports have referred to these features in hypervitaminosis A, but no correlation has been made with normal morphologic changes in the epidermis and its appendages or with known physiological functions of the skin.

Eye Symptoms.—For the sake of completeness, it must be mentioned that exophthalmos, though in our case of questionable connection with the hypervitaminosis, has been a feature seen by several investigators in laboratory animals receiving high doses of vitamin A.[15] (Also excess vitamin A has been said to have no effect on dark adaption.[16])

Laboratory Studies.—As in previous investigations in infants and laboratory animals with hypervitaminosis A, few detectable changes in the blood picture were present in our patient (table). On the other hand, in contrast to some of the previous reports, Mrs. N. R. had no abnormalities in alkaline phosphatase and mineral metabolism in blood or urine studies done several days after the vitamin A ingestion was stopped. The total plasma proteins, red blood cells and hemoglobin, repeatedly re-

ported as below normal in some of the children with this syndrome, were normal in this instance.

Several abnormalities were present in our patient: the white blood cells were increased in number (13,000 per cubic millimeter) on the initial study and subsequently receded to normal figures (7,400 and 6,500), which were similar to counts done on the patient over a number of years. An increment in monocytes was noted on three separate occasions, a decrease being noted on the last count.

As found by all other investigators, the vitamin A level was much higher than normal. When the supplementary vitamin A intake was stopped, within a four month period a definite recession toward accepted normal figures occurred. During the period when no supplemental vitamin A was being taken, the total carotenoids rose to a figure slightly above normal. Concomitantly, the originally elevated total lipids, lipid phosphorous and fatty acids fractions reverted toward standard figures. It may be worthy of particular note that the cholesterol levels remained within the normal range throughout.

All other blood studies and urinalyses gave normal findings in every respect. The fact that no history or no evidence of renal disease was elicited indicates the probable lack of relation between the mechanisms in our case and the interesting observation of Popper and his associates [17] who found that "hypervitaminosis A judged by plasma levels was found in disease of the nephritic type." Apparently, even in the absence of liver damage, the destruction of the kidney parenchyma either causes retention of a protective substance or decreases the production of a substance destructive for vitamin A. Therefore, feeding of excessive vitamin A produces a much higher vitamin A blood level in persons with nephritis than in normals. Whatever the mechanism, it is certain that "endogenous hypervitaminemia A" (i. e., without apparent excessive intake) does occur and must be kept in mind in the presence of isolated reports of blood abnormality.[18] The history of excessive vitamin A intake, variations in the vitamin A tolerance curve, knowledge of the patient's general physical condition and the height of the blood vitamin A levels usually permit the ready differentiation between endogenous and exogenous hypervitaminemia A. In our patient, the evidence points unequivocally to the exogenous form.

Other Features of Hypervitaminosis A.—Several aspects of hypervitaminosis A previously described in infants and children were absent in the present case. These additional components were hepatomegaly, splenomegaly, hypochromic anemia, depressed serum proteins, elevated alkaline phosphatase, clubbing of fingers and an abnormal appetite for butter and fish liver oils. It is very likely the variations in response of human beings to an overdosage of the same vitamin are dependent on such factors as the amount, the length of time and how often the medication is taken. The different physiological and biochemical demands and stresses in each person and in each age group, and even in each organ or structure within an organ, doubtless play important roles in vitamin A metabolism and in the determination of the pictures produced by excess or deficiency of intake.

Many other factors must influence the blood levels and the susceptibility of a person to be overwhelmed by vitamin A. One of these factors is the form or preparation in which the vitamin is taken or administered (in food or a supplement); some available preparations are oils, others acetates or alcohols, while still others have emulsifying agents added.[19] The status of the gastrointestinal tract, including its enzymes, flora and physical and chemical emulsifying capacity, as well as the status of the intestinal wall, and the transport system, including the ability of the chylous fluid and blood to carry the vitamin, are other factors. The status of the liver, thyroid, kidney and other internal organs and the interrelationship between them and vitamin A would also be important. Different periods of growth, bodily stress and development obviously vary the need for the vitamin. The storage areas, primarily the liver, and the ability or inability to store or release the vitamin [20] should also be considered. The form of the vitamin, whether an alcohol or not, has a great deal to do with this.[12c] The destruction, excretion and conversion of the vitamin, and the states, functions and needs of the organs of response, of the "target structures" at the time the vitamin is exhibited (for example, the state and needs of the individual hair follicle at the moment; the momentary rate and form of activity of the sebaceous glands; the quiescence or activity of bone growth) are other influencing factors.

Vitamin A Therapy.—It is not the purpose of this paper to review all the indications for vitamin A therapy. However, large doses, 100,000 to 500,000 international units daily, taken for varying or even indefinite periods of time, are being advocated for the treatment of many conditions.[21] Of significance in this regard is that the advocated therapy sometimes has little clinical or experimental justification.

In view of the present widespread use of extremely large doses of vitamin A, it is remarkable that scarcely a reference has been made to clinical signs of "toxic" hypervitaminosis A occurring in patients receiving large doses for relatively long periods of time. Fortunately, in most patients the zone between adequate prophylactic and therapeutic doses and the toxic doses appears to be very wide. Nevertheless, the present case again emphasizes that the physician administering large doses of vitamin A must be on the lookout for signs and symptoms of toxicity and should have regular blood examinations for vitamin A levels performed on all patients on high doses for periods of more than a few weeks.

V.: Vitamin A, Its Effect on Acne: A Study of 100 Patients, Northwest Med. 42: 219 (Aug.) 1943.

With the advent of many high potency preparations, some with added emulsifying agents (wetting agents), the possibility of overdosage with vitamin A is greater and increases the need for recognizing the syndrome of hypervitaminosis A, which until now may often have been overlooked.

Speculations on Vitamin A Toxicosis as Related to the Skin.—Nearly all references to hypervitaminosis A discuss the blood findings,[22] the apparent similarity to infantile cortical hyperostosis,[23] and the interrelation of the vitamin metabolism with the liver and hormonal glandular system of the body. One of the most striking features of our case is the manifest, undeniable and far reaching resemblance between the skin changes presented by this hypervitaminotic state and those characteristic of hypovitaminosis A.[14] Even without questioning the patient and on mere clinical inspection, experienced dermatological observers would immediately and certainly consider, first, hypovitaminosis or avitaminosis A, and, second, hypothyroidism, as the probable underlying cause of this woman's difficulty. We believe that this aspect of the syndrome of hypervitaminosis A deserves further comment.

Excellent experimental and clinical evidence reveals a definite relation between the thyroid and vitamin A. For example, the simultaneous administration of vitamin A and thyroxin prevents a rise in the basal metabolism.[24] Sadhu and Brody have demonstrated that in rats large doses of vitamin A cause a decrease in thyroid size and reduce the basal metabolic rate while allowing normal growth. It is postulated that the thyrotropic hormone is counteracted in some manner by part of the vitamin A, as is the action of the injected thyroxin on end organs and enzyme systems.[25]

Most persons with hypothyroidism have low vitamin A levels and high carotenoids. It is presumed that thyroid activity is needed for the conversion of carotene to vitamin A; thus, it has been shown that when thyriod therapy is given to raise the basal metabolic rate and lower the cholesterol level, the altered carotene and vitamin A values tend to return to normal.[26] Low serum levels of vitamin A in cretins showed little change when carotene was administered orally. Moreover, administration of desiccated thyroid stimulates and thiouracil prevents the absorption of beta carotene from the intestinal tract of rats.[27] Patients with exophthalmic goiter receiving a diet high in cod liver oil and low in fat gained weight; the basal metabolic rate was also reduced.[28] Most pertinent is the observation of Josephs, who stated, regarding hypervitaminosis A, "It may look like hypothyroidism due to an excess of thyroid antagonist not diminished thyroid gland activity. Relative failure of the thyroid may explain the persistence of high lipid levels and hypothyroid symptoms." [1]

Much about our patient fitted into the picture of hypothyroidism as evidenced in the skin and other systems. However, it is not by any means clear by just what mechanisms the skin changes of either hypovitaminosis or hypervitaminosis A are brought about nor the reason for their striking resemblances. To just what extent thyroid function plays the role of a common factor is also as yet unelucidated.

The possibility of therapy with thyroxin was considered in our patient but discarded because of conflicting reports as to its efficacy.[29] One group has even stated that the symptoms of hypervitaminosis A in laboratory animals were enhanced by administration of thyroid.[29a] Since apparent spontaneous recovery occurs from the toxic manifestations of hypervitaminosis A, no active therapy was instituted in our case. As was to be expected, the result of the cessation of the excessive vitamin A intake was a satisfactorily prompt and complete disappearance of the signs and symptoms.

SUMMARY

The observations and course of a case of hypervitaminosis A, apparently the first to be reported in an adult, are presented. Several possible features of the syndrome not observable in infants or children are described in the adult (e. g., menstrual changes, absence of radiologic changes of the bones, chloasma or Riehl's melanosis-like pigmentation). The effects and mechanisms of excessive vitamin A on various organs and systems and, in particular, on the structures of the skin are discussed. The resemblances between the changes of hypervitaminosis A, hypovitaminosis or avitaminosis A and hypothyroidism are described, and some thoughts on the possible interrelations are submitted.

Hippocratic Oath.—The modernisation of the Hippocratic Oath by the World Medical Association, known as the Declaration of Geneva (1948), is known to very few and is worthy of note. It runs—

Now being admitted to the profession of Medicine, I solemnly pledge to consecrate my life to the service of humanity. I will give respect and gratitude to my deserving teachers. I will practice medicine with conscience and dignity. The health and life of my patients will be my first consideration. I will hold in confidence all that my patient confides in me. I will maintain the honour and noble traditions of the medical profession. My colleagues will be as my brothers. I will not permit consideration of race, religion, nationality, party politics or social standing to intervene between my duty and my patient. I will maintain the utmost respect of human life from its conception. Even under threat I will not use my knowledge contrary to the laws of humanity. These promises I make freely and upon my honour. —Robert Richards, M.D., *Surgo*, February 1951.

BOECK'S SARCOID WITH COMPLETE HEART BLOCK MIMICKING CAROTID SINUS SYNCOPE

REPORT OF A CASE

Samuel Simkins, M.D., Philadelphia

Sarcoidosis is a disease with myriad facets concerning many of which relatively little is known. This is due chiefly to the relative benignity of the disease and consequent lack of autopsy material. Only 66 autopsied cases have been recorded in the literature.[1] Of these, only 15 cases presented direct cardiac involvement. Most of the cases were asymptomatic insofar as cardiac manifestations were concerned. Bernstein and others [2] in 1929 published the first report in the English literature of an autopsied case with cardiac involvement, their patient being a 52-year-old white man with no cardiac symptoms and nodules in the epicardium, as well as invasion of the superficial myocardial fibers. In the English literature, only 12 other authenticated autopsied cases are described.[3] One of Longcope and Fisher's cases,[3i] a 42-year-old Negro man with a marked cor pulmonale, showed sarcoid lesions throughout the myocardium and pericardium plus a large dense scar in the interventricular septum that accounted for a long history of auriculoventricular dissociation. In the non-English literature dealing with cardiac involvement in autopsied cases,[4] Schaumann [4b] emphasized, in 1914, the fact that sarcoidosis is a generalized disease. In the group of 15 autopsied patients with cardiac involvement, note should be taken of the predominance of the male sex and the high percentage of Negroes in the American literature. There is probably little doubt that many cases previously reported as tuberculous in reality represent myocardial sarcoidosis.[5] More recently the situation has been confused even more by the realization that the sarcoid lesion is found in many conditions other than sarcoidosis.[6]

Salvesen [7] in 1935 was the first to emphasize the importance of electrocardiographic changes in sarcoidosis. In two of the four cases he reported, there were changing abnormalities in cardiac mechanism with repeated bouts of paroxysmal tachycardia, transient right bundle branch block, and constant tachycardia. Cotter's [3h] patient showed an electrocardiographic picture changing from that of sinus tachycardia, with arborization block and low voltage, to that of auricular fibrillation, complete heart block, and shifting pacemaker. Varying degrees of cor pulmonale are to be expected in many cases of sarcoidosis in view of the extreme pulmonary involvement commonly found, often with considerable fibrosis.[8] The diagnostic import of tachycardia during afebrile phases of the disease as indication of possible cardiac involvement has been mentioned.[9] Sudden death, described in three cases,[10] has been attributed to the presence of active lesions extensively involving the myocardium, together with pronounced fibrosis.[1c] Many cases of cardiac failure, even of extreme degree, improve and may even be restored to full compensation.[11]

REPORT OF A CASE

V. C., aged 42 at that time, was first examined Feb. 6, 1939, on account of fainting spells and attacks of weakness. The first syncopal attack had occurred suddenly in 1932, was diagnosed as a "heart attack," and the patient had been kept in bed for 15 weeks. At that time the pulse rate was noted as 30. Subsequently she felt well. A second syncopal attack occurred in January, 1938, this time accompanied by pain in the left side of the chest anteriorly, dyspnea, sweating, and cyanosis. Again the diagnosis of "heart attack" was made, and the patient was kept in bed six months. She felt fairly well afterward until early in 1939 when she began to complain of occasional fleeting substernal "tightness" and interscapular pain, as well as fatiguability and weakness. In 1936, a hysterectomy with unilateral oophorectomy had been performed on account of uterine fibroids. Recently she had been suffering from occasional hot flashes, sweats, and chilliness.

Examination disclosed a middle-aged, stockily built, cooperative, alert woman of medium height. The pulse rate was 66, and the blood pressure was 104/78 mm.Hg. Aside from a loud low-pitched murmur localized at the apex, the heart was essentially normal. Fluoroscopy of the chest revealed nothing of note. The electrocardiogram was normal; the fasting blood sugar was 111 mg. per 100 cc.; the blood count and urinalysis were normal, and the result of blood Wassermann test was negative. The menopausal symptoms yielded promptly to the administration of estrogens. The pulse rate varied between 60 and 76, and the blood pressure between 104/66 and 110/74 mm.Hg.

On Aug. 5, 1941, while on vacation, she fainted. The pulse rate was 46. On her return home Aug. 19, 1941, physical examination

was essentially as noted in 1939. The left carotid sinus was normal. Moderate pressure of a few seconds' duration over the right carotid sinus promptly produced dizziness, pallor, dimness of vision, weakness, and a sensation of impending syncope. The blood pressure and pulse rate were unaffected. Pressure over other portions of the neck, as well as over the carotid arteries below the carotid sinuses, produced no symptoms. Repetition of right carotid sinus stimulation produced syncope of a few second's duration with symptoms duplicating those of the attack she had suffered on her vacation. She was hospitalized Aug. 24, 1941, to Sept. 10, 1941. The electrocardiogram was normal and was essentially unchanged during syncope readily induced by right carotid sinus pressure. At no time was the blood pressure or pulse affected. Result of the tuberculin skin test was negative. An oral glucose tolerance test was normal. Blood sugar taken during syncope was 140 mg. per 100 cc. The basal metabolic rate was —3%, and the blood cholesterol was 220 mg. per 100 cc. Spinal fluid examination was completely normal. The patient was discharged with the diagnosis "carotid sinus syncope, cerebral type."

On Sept. 20, 1941, she complained of extreme fatigue followed within a few hours by distinct drowsiness, sweating, ashen hue, swelling in the region of the right parotid gland, and finally unconsciousness that lasted for two hours. The pulse rate was 54 with occasional extrasystoles. Three similar attacks occurred the same day. These attacks were unquestionably much severer than those previously suffered and much more prolonged. Thereafter the patient improved steadily, except for very mild attacks of dizziness accompanied by some dimness of vision, and remained thus through 1946. Stimulation of the right carotid sinus produced only very mild presyncopal manifestations.

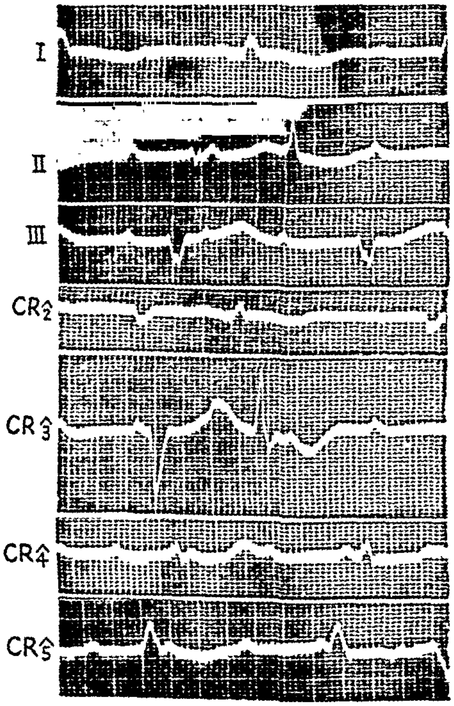

Fig. 1.—Electrocardiogram taken March 14, 1947, disclosing complete auriculoventricular block with a ventricular rate of 44 and auricular rate of 110, ventricular extrasystoles, and left bundle branch block. The P waves and the S-T interval are normal. The QRS complexes are slurred and small, their duration being 0.12 seconds. The T waves are inverted in leads 1 and CR_5.

On March 13, 1947, she suddenly developed weakness, dyspnea, and dizziness. The pulse rate varied between 30 and 48, with occasional extrasystoles. At this time pressure over the right carotid sinus, with the patient recumbent, produced no effects; pressure over the left carotid sinus caused the rapid onset of pronounced weakness, dizziness, and pallor. The pulse slowed slightly and became very irregular. The blood pressure was unchanged. Physical examination otherwise was normal. At no time during the course of the illness did superficial adenopathy appear. A nocturnal attack of acute pulmonary edema developed. She was hospitalized the next day. An electrocardiogram (fig. 1) taken later the same day disclosed complete auriculoventricular block with a ventricular rate of 44, ventricular extrasystoles, and left bundle branch block. An electrocardiogram (fig. 2) taken March 18, 1947, showed a cardiac rate of 79 with minor grade auriculoventricular block and right bundle branch block. A bedside caloric test was normal. The fundi were normal. Roentgenogram of the skull showed hyperostosis frontalis. The blood count was normal, as was complete examination of the spinal fluid. On March 25, 1947, an electrocardiogram showed essentially the same picture as on March 14, 1947. Intravenous administration of atropine sulfate (grain 1/75 [.87 mg.]) followed by carotid sinus stimulation had no noteworthy effect. Thereafter the pulse rate varied in erratic fashion between 44 and 84 per minute, grossly irregular in volume and rhythm. On March 26, 1947, the patient lapsed into a stupor lasting eight hours from which she could not be aroused. No abnormal neurological signs were present. Several episodes of syncope occurred April 1, 1947, followed the next day by sudden cyanosis and death.

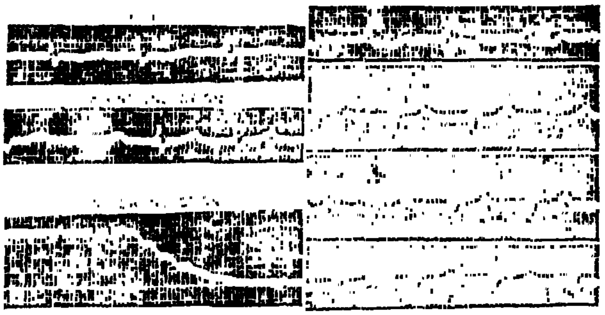

Fig. 2.—Electrocardiogram taken March 18, 1947, disclosing minor grade auriculoventricular block and intraventricular conduction defect, predominantly right bundle branch block. In one of the lead 2 tracings during injection of atropine, partial auriculoventricular block of the Wenkebach's period type occurred. The cardiac rate was 79, with regular sinus rhythm. The P waves are normal. The QRS complexes of 0.10 seconds' duration are slurred. The duration of the P-R interval was 0.40 seconds. The S-T interval is depressed in CR_1, and T waves are inverted in LL-1.

Report of Autopsy.—Autopsy permission was limited to a small thoracic incision. The pleurae show adhesions over the entire right upper lobe. The pericardium, peritoneum, ascending aorta, and pulmonary arteries are normal.

The heart is dilated in all chambers, right more than left. Numbers of patches seen beneath the epicardium are white in contrast with the yellow fat. The largest, 2 by 1 cm., is seen in the outer wall of the left ventricle at the junction of the upper and middle thirds and extends about 1 cm. into the cardiac muscle. The patch is slightly firmer than the muscle itself and is not encapsulated. Other similar patches of variable size are dotted around this one and are also found here and there in other parts of the heart. When the ventricles are opened, similar patches are seen in both, more in the left than the right. The largest patch involves the entire thickness of the septum in the region of the auriculoventricular bundle (fig. 3). It is seen on the endocardium just below the aortic valve as an irregular thickening with numerous pinpoint projections on the surface. This area extends for 2½ cm. below the septal (right posterior) cusp and is 4 cm. in width. There are a few vegetation-like lesions on the aortic cusp, particularly at the junction of the right posterior and anterior cusps, as well as irregular white thickening in all the cusps. When the area of the auriculoventricular bundle is sectioned, the wall is found replaced by tumor except for a few striations, which may be remains of muscle fibers. Away from the tumor patches the muscle is congested and in the right ventricle is somewhat flabby: right ventricle 0.3 cm., left ventricle up to 1.5 cm., aortic valve 7½ cm., pulmonary valve 8.5 cm., mitral valve 9.0 cm., tricuspid valve 10 cm. The mitral valve is moderately thickened throughout. The tricuspid and pulmonary valves appear normal, but there is growth in the papillary muscles of both the tricuspid and mitral valves.

The lungs show one or two nodules the size of a large pinhead in both upper lobes. The spleen is large and congested. The lymph nodes around the trachea and pericardium, and especially in the anterior mediastinum, are large and filled with pale, soft growth. The kidneys, gastrointestinal tract, liver, gall bladder, pancreas, and adrenals are normal.

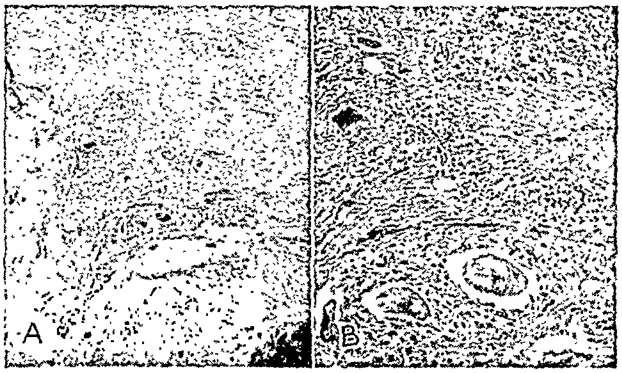

Fig. 3.—Photomicrographs of section of auriculoventricular bundle and aortic valve taken at area where the aortic valve joins the muscle. Note the tubercle-like structures, pronounced fibrosis, and presence of vacuolated material. (*A*, × 25; *B*, × 90.)

Histological Diagnosis.—Examination of the heart revealed the following: Tumors all have the same characteristics. They present tubercle-like nodules consisting of concentrically arranged endothelioid cells and very numerous giant cells of the Langerhans or tuberculous type. The giant cells are often extremely large. The nuclei are very numerous. They are crowded, sometimes in the center of the cells, sometimes at the periphery. The protoplasm of the giant cells often has a granular appearance and in some cells has an ovoid lining in contrast with the usual branching protoplasm. More recently formed tubercles show a fibrillary matrix which stains red with the Goldner modification of the Masson trichrome stain and may be fibroid. In the older tubercles a few collagen fibers are seen. There is no caseation. Several sections studied with the Ziehl-Neelsen carbolfuchsin stain are negative for the tuberculosis bacillus. The tubercles are sharply outlined and are surrounded by fibrous tissue. There are seldom any lymphocytes to be seen. In short, the tubercles are typical of the structures seen in Boeck's sarcoid. The heart muscle is infiltrated and is in the process of being slowly destroyed by these structures (fig. 4).

The lungs show circumscribed lesions similar to those noted in the heart. The liver shows moderate congestion and slight edema. In one place under the capsule, there is a characteristic sarcoid lesion, and smaller lesions are found in some of the portal areas. Several mediastinal lymph nodes were examined and showed characteristic lesions of Boeck's sarcoid.

COMMENT

The case reported here has many puzzling features which make it somewhat difficult to fathom, even in retrospect. There seems to be little question that the first attack of syncope in 1932 was on the basis of a hyperactive carotid sinus reflex. The bradycardia placed the type as predominantly vagal.[1b] In August, 1941, the patient apparently suffered a severe attack of vagal carotid sinus syncope. Yet in examination two weeks later, the attacks seemed to be typical of "cerebral" carotid sinus syncope.[12] The diagnostic criteria of cerebral carotid sinus syncope [13] were fairly completely met; namely, reproducibility of the attack by stimulation of the affected carotid sinus with no change in the blood pressure or pulse, failure to influence the attack by pressure over the carotid arteries below the carotid sinuses, and lastly, failure to produce an attack by stimulation of any extracarotid sinus areas in the neck or elsewhere in the body.[14] Infiltration of the region of the sensitive carotid sinus with 1% procaine hydrochloride for differentiation of hysteroneurosis was not done.[15] Neither was electroencephalography performed. What escaped emphasis at that time (September, 1941) was the development of what was apparently a mild parotitis and an unusually prolonged syncope. In retrospect, it is possible that this marked the clinical onset of sarcoidosis. The subsequent six years' relatively good health is not uncommon in sarcoidosis, as the disease is notoriously slowly progressive in some areas and simultaneously recessive in other areas.

The terminal phase of the disease developed with the onset of weakness, inconstant complete heart block, and acute pulmonary edema. The absence of peripheral adenopathy during the course of the entire illness is noteworthy but not uncommon.[16] It is of interest that the right carotid sinus at this time was relatively insensitive, whereas the hitherto normal left carotid sinus now exhibited sensitivity. The shift in hypersensitivity from one carotid sinus to the other has been noted on several occasions.[17] Speculation concerning the possible involvement of the carotid sinuses in this case by sarcoid lesions, with recession of the lesions in the right carotid sinus and concomitant involvement of the left carotid sinus, is of interest. The association between hypersensitivity of the carotid sinuses and coronary artery disease,[18] as well as the occurrence of anginal symptoms,[19] has received

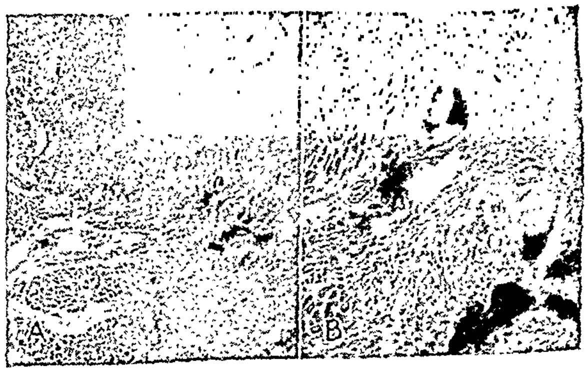

Fig. 4.—Photomicrographs of septum and left ventricle. Most of the wall is destroyed and replaced by the sarcoid process. Fibrosis is pronounced. (*A*, × 25; *B*, × 90.)

strong emphasis. The development of prolonged stupor terminally, with no focal neurological signs, was a puzzling clinical feature. Cerebral involvement in sarcoidosis has received relatively scant notice.[20] Most of the cases described had striking neurological aberrations. In the present case, possible sarcoid involvement of the brain stem is indicated by the lethargy that developed. The present case helps to unmask the often stressed benignity of sarcoidosis and poses the potentially serious prognosis of the relatively common cardiac involvement.

SUMMARY AND CONCLUSIONS

A case of generalized sarcoidosis with massive involvement of the myocardium and partial involvement of the auriculoventricular bundle is presented. The possible linkage of the sarcoidosis in this case with a 15 year history of carotid sinus syncope is discussed. Cardiac involvement by sarcoidosis is relatively common and heightens the gravity of the prognosis.

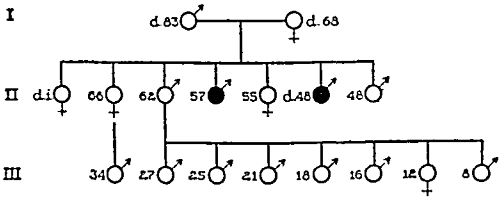
FAMILIAL INCIDENCE OF PRIMARY CARCINOMA OF THE JEJUNUM

James E. Pridgen, M.D., Charles W. Mayo, M.D.
and
Arthur G. Steinberg, Ph.D., Rochester, Minn.

In reviewing the literature one finds that carcinoma of the small intestine forms from 0.029 per cent [1] to 6 per cent [2] of the gastrointestinal malignant lesions. After an exhaustive survey more than 550 cases of adenocarcinoma of the jejunum and ileum were found. However, only too rarely are carcinoid tumors segregated from primary carcinomas of the small intestine. Primary carcinoma of the small intestine exclusive of carcinoids was found to constitute about 1 per cent of the gastrointestinal malignant lesions in recent years at the Mayo Clinic.[3] Even more unusual than the low incidence of this lesion is the occurrence of a familial tendency. Only one case of familial incidence was found among the 63 cases in which carcinoma of jejunum and ileum was surgically treated from 1907 through June 1947, at the Mayo Clinic; this series of cases is discussed elsewhere.[4] Foster's description [5] of adrenocarcinoma occurring in father and daughter is the only report found in the literature of a familial incidence of this lesion in the jejunum and ileum.



Pedigree of two brothers having primary carcinoma of the jejunum. Data are presented as of June 1949. The white circles indicate the normal members of the family; the black circles, the affected members.

The present pedigree (chart) is reported in the hope that in time sufficient records may be accumulated to permit an analysis of the genetic factors, if any, in the etiology of this disease. Only members II-4 and II-6 were affected; all the others in the pedigree were reported by II-4 to be unaffected.

REPORT OF CASES

CASE 1 (II-4 in pedigree, chart).—*History.*—A white farmer, aged 53 years, was admitted to the clinic June 12, 1944, complaining that he felt pain in the left upper quadrant of the abdomen when having a bowel movement. For 18 months he had noted weakness and shortness of breath. Eight months before admission occult blood was found in his stools, and anemia was diagnosed. He was given ferrous sulfate orally, and his condition temporarily improved. For two months he complained of recurrent weakness, anorexia and intermittent cramps in the left lower quadrant of the abdomen, lasting for one hour after meals. He had alternating constipation and diarrhea, passed much flatus and had lost 45 pounds (about 20 Kg.) in one and a half years. He had received three blood transfusions in the six weeks before admission. His past medical history was noncontributory.

On examination the temperature was 98.6 F., the pulse rate 90, the respiratory rate 20 and the blood pressure 120 mm. of mercury systolic and 65 mm. diastolic. He was pale and anemic looking and had obviously had recent loss of weight. The other essential pathological changes were limited to the abdomen and consisted of a mass palpated in the left lower quadrant, visible peristalsis and borborygmus.

Laboratory Report.—The results of roentgenologic studies of the chest, stomach and colon were normal. Studies of the small bowel revealed carcinoma of the jejunum within 3 feet (about 91 cm.) of the ligament of Treitz. A plain film of the abdomen showed no distention of the small bowel. The concentration of hemoglobin was 7.65 Gm. per 100 cc. of blood (15 Gm. equals 100 per cent). The erythrocyte count was 3,230,000 per cubic millimeter, and the leukocyte count was 6,300. The sedimentation rate (Westergren) was 53 mm. in one hour. Analysis of gastric contents revealed 16 units of free hydrochloric acid and 20 units of total acid. The results of proctoscopic examination were negative.

Operative Report.—On June 24, 1944 the abdomen was opened through a primary left upper rectus muscle-retracting incision. No distant metastasis was found, and the liver was free of involvement. The lesion was found about 3 feet (about 91 cm.) below the ligamant of Treitz, almost obstructing the lumen of the bowel, and perforated onto the descending colon. This lesion was resected en masse, the tumor being removed widely with the mesentery, and an end to end jejunojejunostomy was performed aseptically over a three-bladed clamp. Resection of the

descending colon was next accomplished, followed by colocolostomy, also with use of the three-bladed clamp.

Pathology Report.—The specimen consisted of 55 cm. of jejunum and 15 cm. of attached colon. The lesion was a grade 3 (Broders[6]) annular ulcerative perforating infected adenocarcinoma of the small intestine, 15 by 5 by 2.5 cm., with peritoneal involvement. Nodes had been the site of inflammation. The lesion was type B of Dukes's classification.[7] The colon was attached to the small intestine but not involved directly by the carcinoma.

Prognosis.—As of June 1950, the patient had no symptoms and was doing well.

Case 2 (II-6 in pedigree, chart).—*History.*—A farmer, aged 47 years, a brother of the preceding patient, was admitted to the clinic April 3, 1945. For five months he had complained of vague pains in the right lower quadrant of the abdomen, becoming sharper at certain times. He felt well on arising but had the pain in the evening. He had a sensation of fulness most of the time with bloating, but no distention or vomiting. He complained of early fatigue. Tumor of the cecum was diagnosed elsewhere. Two months before admission he had one severe attack of cramping pains in the right lower quadrant of the abdomen which awakened him from sleep.

On examination the temperature was 98.6 F., the pulse rate was 84 and the blood pressure was 110 mm. of mercury systolic and 70 mm. diastolic. The only essential abnormal finding was a mass in the left lower quadrant of the abdomen near the umbilicus.

Laboratory Report.—The results of roentgenologic examination of the chest, stomach and colon were normal. Studies of the small bowel revealed a carcinoma of the lower part of the jejunum. The concentration of hemoglobin was 7.8 Gm. per 100 cc. of blood (15 Gm. equals 100 per cent). The red blood cell count was 3,340,000 and white blood cell count was 5,800 per cubic millimeter. The results of examination of urine were normal, as were those of proctoscopic examination. The sedimentation rate was 29 mm. per hour.

Operative Report.—On April 14, 1945 the abdomen was opened through a primary upper middle right rectus incision. There was extensive nodal involvement, but the liver was free of metastasis. The lesion was found about 4 feet (about 122 cm.) from the ligament of Treitz perforating onto the lower part of the sigmoid colon. Resection of about 3 feet (about 91 cm.) of midjejunum was performed, and jejunojejunostomy was established over the three-bladed clamp. The involved portion of the lower sigmoid was removed en masse with the tumor, and an end to end anastomosis was effected with the three-bladed clamp.

Two courses of x-ray treatment were given subsequently over the abdomen.

Pathology Report.—The specimen consisted of 140 cm. of jejunum and 15 cm. of attached colon. The lesion was an annular, ulcerative, perforating, necrotic mucous adenocarcinoma, grade 4 (Broders), 8 by 6 by 3 cm. There was extensive peritoneal nodal and colonic involvement; the lesion was type C of Dukes's classification.

Prognosis.—The patient died Feb. 16, 1946.

COMMENT

These two cases are reported because of the rarity of primary carcinoma of the jejunum and ileum and the even greater rarity of a demonstrated familial tendency.

Of additional interest is the fact that these two cases present clinical signs and symptoms of anemia as well as chronic intermittent obstruction of the small bowel. Roentgenologic studies of the small bowel were accurate in both the diagnosis and the location of the lesions. One of the brothers is still alive more than six years after the time of his operation.

DIAGNOSTIC AND THERAPEUTIC NERVE BLOCKS: NECESSITY FOR ROENTGENOGRAMS

John W. Pender, M.D.
and
David G. Pugh, M.D., Rochester, Minn.

The use of roentgenograms is necessary in performing diagnostic and therapeutic blocks for two reasons: (1) for more accurate placement of the needles and (2) as an objective record of the position of the needles at the time the anesthetic solution was injected.

Since diagnostic nerve blocks are used to determine the pathways of pain impulses, the problems involved are different from those encountered when nerves are blocked for the purpose of producing anesthesia for surgical procedures. When a patient presents himself for the relief of pain, his physician attempts to find the etiological factor that is causing the pain and to give the patient relief by removing the cause. Such an ideal course of events cannot always be achieved, sometimes because the source of the pain cannot be determined and sometimes because the diagnosed source of the pain cannot be eliminated. In such situations the physician's next recourse is to locate the peripheral nerves over which the impulses are traveling to the central nervous system. The peripheral nerves transmitting pain impulses can be singled out by individually blocking the nerves that supply the involved part and noting the result on the pain. The needles must be placed precisely and only small amounts of anesthetic solution may be injected, in order to avoid involving by the individual injections more nerve trunks than intended. The usefulness of the entire procedure may depend upon the selectivity with which separate nerves can be blocked. More accuracy and precision are therefore necessary in the placement of the needles for diagnostic nerve blocks than for nerve blocks for surgical anesthesia. In producing surgical anesthesia more needles may be used and larger volumes of anesthetic solution injected as indicated until the desired result is obtained. The knowledge as to which individual nerves have been interrupted is not necessary for the success of nerve blocks for surgical procedures but is the basis of the entire procedure of diagnostic nerve blocks.

Once the tip of the needle has disappeared from sight beneath the skin, its position can be determined only by

---

From the Section on Anesthesiology (Dr. Pender) and the Section on Roentgenology (Dr. Pugh), Mayo Clinic.

Read before the Section on Anesthesiology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

(1) the relationship of the visible part of the needle to surface landmarks and (2) the palpation of deeper bony landmarks by means of the needle. While adequate in most instances for producing surgical anesthesia, such gross information about the position of the tip of the needle has not been accurate enough for many diagnostic blocks, even when performed by skilled anesthesiologists with many years of experience with local anesthesia. The use of roentgenograms enables even the less experienced physician to determine accurately the position of the tips of the needles and eventually to place them in the correct anatomic location for the injected anesthetic solution to have the desired effect. The farther below the skin the injection must be made, the more difficult the exact placement of the tip of the needle becomes and the more imperative the necessity for the use of roentgenograms. In figure 1 *a* the tip of the needle appears to be near the surface of the body of the third lumbar vertebra in apparently good position for blocking the lumbar sympathetic trunk. In figure 1 *b*, however, it is apparent that the tip of the needle is too far anterior to the body of the vertebra; hence the needle was withdrawn to the position shown in figure 1 *c*, and a good block resulted.

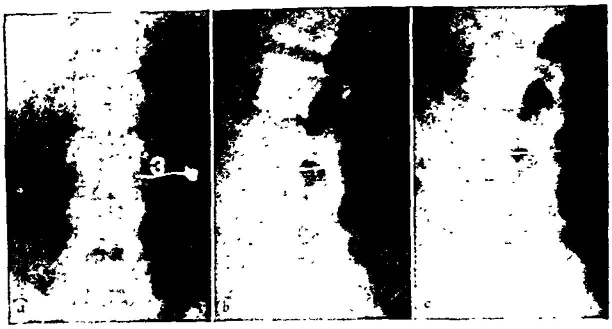

Fig. 1.—Placement of needle for diagnostic block of the lumbar sympathetic trunk. In the anteroposterior view, *a*, the position of the needle appeared satisfactory, but in the lateral view, *b*, the tip of the needle was seen to be too far anterior. The needle was partially withdrawn and in the lateral view, *c*, was seen to be in good position.

Surface landmarks are too indefinite for good localization of needles in patients with normal anatomic structure. In patients with deformity and abnormal structure a placement of needles for accurate nerve blocking is impossible without the aid of roentgenograms. An example is shown in figure 2. The patient had congenital abnormalities with a marked thoracic kyphosis and backache. It was desired to block the paravertebral nerves involved in the deformity. In spite of the fact that all palpable landmarks were hopelessly confused, the use of roentgenograms made it possible to place the needles as shown in figure 2 *a* and *b* and to relieve the patient's pain. On the basis of the result of the nerve block, it was elected to do a bone graft on the affected vertebrae, and the patient was afforded permanent relief.

Roentgenographic records of nerve blocks are valuable because, first, they make it possible for the diagnostic block to be repeated accurately and, second, they are convincing proof to the surgeon or other physician reviewing the results of the nerve block as to which nerves actually were blocked. Even the most detailed and lengthy description of how a nerve-blocking procedure was performed will likely not be clear to another physician and certainly will not be thoroughly convincing. In a busy clinic where many patients are being treated, even the same physician cannot repeat accurately the original procedure by following his own description of a nerve block performed several days previously. If, however, the position of the tips of the needles at the first block have been recorded on roentgenograms, the same or a different person at a later time in another place can repeat the original nerve block, provided the needles are shown by a second set of films to be in the same positions as at the original injection. It frequently happens that once the pain pathway has been established by diagnostic nerve blocks with short-acting anesthetic agents, more permanent interruption of the nerves transmitting the pain may be indicated. It is then desirable to repeat exactly the original nerve block which gave temporary relief of pain but to produce a therapeutic nerve block by the injection of a longer-acting agent, such as alcohol, ammonium sulfate solution, or phenol solution.

The use of roentgenograms increases the expense of the original procedure, but in some cases they eventually have proved to be an economy measure. It frequently happens that the patient lives some distance from the specialized clinic where the diagnosis is made and where a series of nerve blocks are prescribed to be performed at regular intervals. The patient need not necessarily have to suffer the loss of time and expense involved in frequent long trips back to the specialized clinic. These repeated nerve blocks may be performed in the patient's home town by his local physician, provided the local physician has the roentgenograms taken at the specialized clinic and reproduces, as proved by his own roentgenograms, the same placement of the needles.

Roentgenograms taken during nerve blocking serve to convince the surgical or medical consultant as to the procedure which was performed. The patient is impressed with the accuracy of the procedure and is more inclined to accept the recommendation which the consultant advises on the basis of the diagnostic nerve block whose accuracy is assured by roentgenograms. Once the nerve pathways of pain impulses have been established by nerve blocking, it may be advisable for such surgical procedures as section of a peripheral nerve, *rhizotomy*,

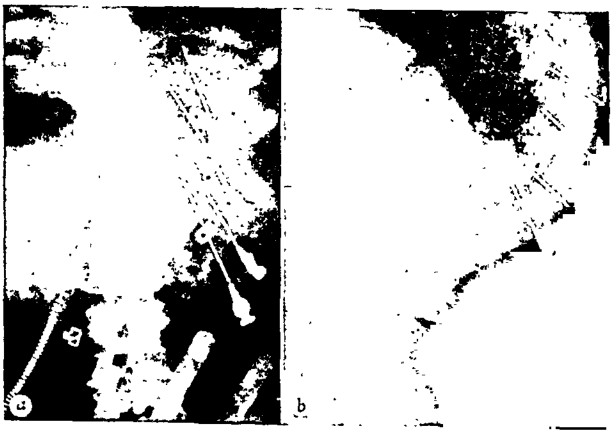

Fig. 2.—Placement of needles for diagnostic thoracic paravertebral somatic block in a patient with marked kyphosis. The points of the needles are shown in both the anteroposterior, *a*, and lateral, *b*, views.

chordotomy, or lobotomy to be performed. The surgeon knows from experience the inaccuracy involved in locating body segments and nerves by counting ribs or vertebral spinous processes. He is, therefore, likely to be reluctant to sever a specific nerve on the evidence resulting from a diagnostic block during which this specific nerve was supposed to have been located by such measures as he knows to be inaccurate. A neurosurgeon justly might refuse to section the left second, third, and fourth cervical nerves because injections made through three needles inserted at intervals caudad to the left mastoid process gave temporary relief of pain. If, however, the neurosurgeon should be shown a roentgenogram such as that in figure 3, he would have to admit that the second, third, and fourth cervical nerves were the ones blocked.

With the exact position of the tips of the needles used for diagnostic nerve blocks made known by roentgenograms, the ability to reproduce the effects of the block by section of the nerve can be predicted convincingly. Section of a nerve is followed frequently by undesirable effects, such as numbness and decrease in motor power, as well as the desirable effect of pain relief. When section of a nerve, or injection of a nerve with alcohol or a similar agent that produces a prolonged effect, is contemplated, it is well first to block the nerve with an anesthetic agent that produces a short temporary effect. This is called a "prognostic block" because it gives the patient a chance to experience the complete effects of section of the nerve before the effects are permanent. If the patient decides that the side effects which follow a block of the nerve are more annoying than the original pain, it is possible to allow the conditions to return to their former state. If the patient desires the results of the prognostic block to be made permanent, such can be promised only if a roentgenographic record has been made of the position of needles used in the prognostic block.

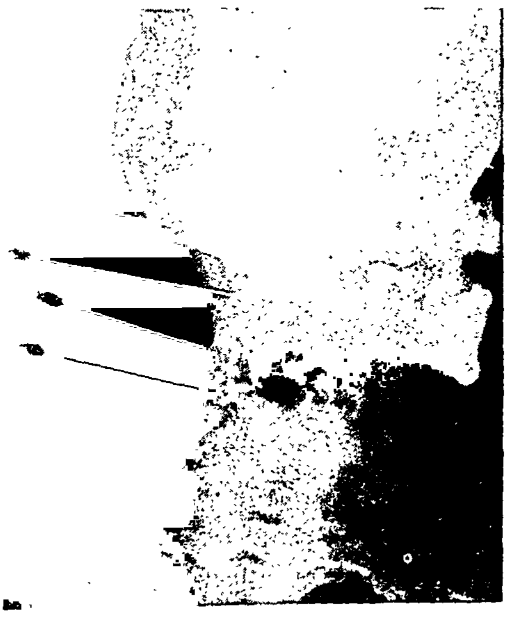

Fig. 3.—Placement of needles for diagnostic block of deep cervical somatic nerves. An artefact caused by a bobby pin appears at the occiput above the three needles.

TECHNICAL SUGGESTIONS

Anteroposterior and lateral roentgenographic views must be made whenever possible to locate the tip of the needle accurately in both planes (fig. 1). When blocks of nerves such as of the stellate ganglion or the obturator nerve are done and a satisfactory lateral roentgenographic view cannot be obtained, the position of the tips of the needles may be located with stereoscopic views.

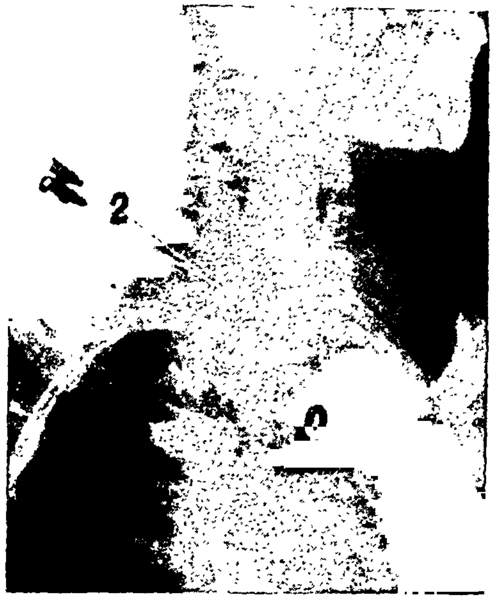

Fig. 4.—Placement of needles for diagnostic block of the stellate ganglion. The lead marker O was placed in the suprasternal notch and used as an aid in positioning the needles.

When the first placement of the needle is found not to be satisfactory, the needle should be left in place and other needles inserted using the first as a guide. The needles may be labeled for identification by placing lead markers near the place where each needle pierces the skin (fig. 1 and 2). Sometimes the discomfort of passage of extra needles can be avoided if a lead marker is first placed on a superficial landmark and a scout (preliminary survey) film taken to learn the anatomic relationship between the position of the lead marker and the nerve to be blocked. In the case represented by figure 4, it was desired to produce a block of the right stellate ganglion with dehydrated (absolute) alcohol for a right shoulder-hand syndrome. By placing a lead "O" in the suprasternal notch and taking a scout film, it was possible to place the tip of the very first needle on the body of the first thoracic vertebra. This position would have been satisfactory for the injection of 5 to 10 cc. of an aqueous diffusible solution of an anesthetic agent such as procaine for a diagnostic block. However, the roentgenogram showed that the tip of the first needle was too far medial on the body of the vertebra to allow the stellate ganglion to be blocked by the injection of 2 cc. of dehydrated alcohol, which does not diffuse widely. Accordingly, a second needle was introduced so that its tip touched the body of the vertebra lateral to the tip of the first needle and near the base of the transverse process where the stellate ganglion lies. The injection of alcohol through the second needle promptly resulted in Horner's syndrome.

SUMMARY AND CONCLUSIONS

Roentgenograms to show the position of the needles must be made when diagnostic and therapeutic nerve blocks are performed. Only by this means can the operator position the tips of the needles with enough accuracy to block individual nerves selectively with the use of small volumes of the anesthetic agent. The roentgenograms serve as objective records which may be utilized later by the operator to obtain an exact repetition of the nerve block either by injection or by some other surgical procedure.

102 Second Ave., S. W.

DIAGNOSTIC AND THERAPEUTIC NERVE BLOCK

GENERAL CONSIDERATIONS

R. Charles Adams, M.D., Rochester, Minn.

The anesthesiologist of today performs a great variety of functions in addition to clinical anesthesia. Among these, perhaps his most important single function and the one that is most gratifying, is the relief of pain.

Pain, in its severer forms, as for example trigeminal neuralgia, migraine, or the various colics, is one of the heaviest crosses the human race has to bear. Usually pain is a danger signal or warning of some beginning disease process, trauma, or physiological upset. It also may be the hang-over effect of past disease processes. It can arise from purely psychic origin, which is perhaps the most difficult to alleviate.

Transient painful processes usually are no problem, but persistent pain, whether mild or severe, over weeks, months, or years can produce serious and far-reaching sequelae, which affect the patients' work, play, and sleep, alter their personalities, and produce changes in every phase of their daily lives.

Until recent years physicians as a whole tended to minimize the importance of persistent pain, particularly if the cause was not readily apparent. Treatment tended to be symptomatic, and many patients who did have a physical basis for their pain were classed as neurotics and treated as such. As a result, they tended to become "doctor's office pests," drifting from one physician to another and frequently falling into the hands of quacks, who preyed on their infirmity to line their own pockets or laid the seeds for beginning drug addiction. It is therefore small wonder that the deserving members of this group of patients frequently lost faith in the ability of the medical profession to help them.

Another contributing factor in holding back the progress of rational therapy of pain has been lack of knowledge of the multitude of pain pathways and mechanisms, the knowledge of which is essential if effective treatment is to be carried out. Some of these pain mechanisms are very bizarre, and even today our knowledge of the complex functions of the central and autonomic nervous systems is indeed elementary. An example of the weird phenomena one encounters in therapeutic block is the relief of hip pain obtained by blocking the anterior, lateral, or posterior femoral cutaneous nerves. On the surface, there is no apparent logical explanation for these results, except that the pain might be caused by muscle spasm lower down over an area supplied by these nerves.

We know much more about pain and the nervous system than we did a few years ago, thanks to the neurophysiologist, neurologist, neurosurgeon, and neuropsychiatrist, but a major portion of this progress, both experimental and clinical, stems from the interest of the anesthesiologist in this field, and it is because of this interest that pain clinics have been established by and under the direction of anesthesiologists over past years. It was not only natural but appropriate that the anesthesiologist largely should take over this field, since his job is to relieve pain in general, and frequently by the injection of nerves or nerve plexuses, in which he has received special training.

At present there are hundreds of pain clinics throughout the country, in addition to a great number of private anesthesiologists who are devoting a portion of their time to this subspecialty. This proves to be one more example of the fact that the specialist in anesthesia may be of aid to his confreres in various other medical specialties.

Broadly speaking, pain falls into two general classifications: (1) due to organic disease; (2) of indeterminate origin. That resulting from some organic disease, such as one of the colics, trauma, angina, previous surgical procedures, or advanced cancer, usually is not difficult to diagnose and treat. Even where pain due to organic disease is severe and persistent, as in inoperable carcinoma, the problem of control is more or less clear-cut. We can inject the pain-carrying nerves and repeat the injections as required; the nerves may be sectioned surgically to provide lasting relief, or, if these measures fail, we are justified in administering whatever analgesics are necessary to make the patient comfortable, since addiction need not worry us in hopeless cases or in cases of elderly patients.

The same cannot be said for the multitude of patients with pain the origin of which is indeterminate, or seemingly so. Many of these patients are young, and we must be assured that whatever treatment we institute will not do them harm or exacerbate their present pain or perhaps even start a different one. This brings to mind a patient into whom I had injected alcohol for pain in the posterior chest wall and had produced good relief. A few days later I met the man on the street and asked him whether the pain in his back was gone still. "Oh, sure, Doc," he replied, "you fixed that one, but this new pain in front is killing me."

From the Section on Anesthesiology, Mayo Clinic.

Read before the Section on Anesthesiology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

This demonstrates how careful we must be in selecting patients for injection therapy, especially when potent and irritating agents such as alcohol are to be used. The psychological approach to this group of patients is just as important in effecting a cure as the ability to place a needle correctly on a nerve.

Most of these patients are skeptical about obtaining relief, having tried a variety of physicians and treatments without results. On the other hand those who are seen for the first time often have the reverse attitude and feel that to be treated is to be cured. Patients with either attitude should be handled in a similar manner, and extreme caution should be exercised in outlining the diagnosis, treatment, and possible results.

It is probably better to promise little in the line of results, although the patient should be encouraged to believe that relief is possible. It is well, however, to explain in detail to the patient the nature of the condition, what may be causing the trouble, the details of the treatment, and what to expect during and after the injection.

The psychological approach to each individual patient is of the greatest importance, for an incorrect approach can either make or break the most effective type of treatment. Therefore, if we are to improve our results in these patients in the future, it is obvious that the internist, neuropsychiatrist, neurosurgeon, and anesthesiologist must work hand in hand, giving one another the maximum cooperation.

Nerve block for pain is of two types: (1) for aid in making or confirming a diagnosis; (2) for actual therapy. The diagnostic block is usually carried out by using a local anesthetic agent the duration of effect of which is limited. Sometimes the use of a local anesthetic agent may provide relief for days and even weeks or months. In any event, if the local block is effective and the diagnosis is established, one must decide on the least drastic therapeutic measure that will give the patient more or less permanent relief. Several choices are available: (1) repeat the local anesthetic injection at periodic intervals; (2) inject a longer-acting agent, to be repeated if necessary; (3) inject dehydrated alcohol; (4) suggest section of the pain-carrying nerves; (5) suggest that the patient learn to live with his pain if it is not too severe or persistent; (6) combine roentgen therapy and injection; (7) combine physical therapy and injection, or (8) combine any of the foregoing with psychotherapy. The choice will depend on the patient's physical and emotional make-up; the cause of his pain, if apparent; the nature, persistence, and severity of the pain; his tolerance to pain; the degree of effectiveness of the preliminary block, and the patient's attitude toward further treatment.

The prime essential, before any attempt is made to treat these patients, is to obtain a detailed history. Even if a previous history has been provided by the referring physician, time will be spent well in asking the patient as many specific questions as one can think of, since this may provide an insight into his physical and emotional problems which might otherwise be overlooked. Questions may be divided into two parts: (1) those asked during the taking of the history; (2) those asked just before, during, or after the block.

During the taking of the history you must have the following information: (1) the site, nature, and severity of the pain; (2) how long the patient has had pain; (3) whether it has increased in severity or remained the same since its inception; (4) whether the pain is increased when pressure is applied over the area, or by position, movement, exercise, and so forth—many neurotic patients interpret pressure as pain and by and large are not good candidates for block; (5) what the patient's own opinion is as to what might have caused the pain in the first place; (6) whether the pain interferes with sleep, and (7) whether the pain can be controlled with acetylsalicylic acid. The last two questions give a fairly accurate estimate of the severity of the pain and what the patient has been taking for it. If, after careful questioning, it appears that a block will be of either diagnostic or therapeutic value or both, certain specific questions must be asked at this time:

1. If the patient has been referred by another physician or physicians, it is well to find out what they told the patient he might expect. Perhaps they minimized the nature and effects of the block; perhaps they overstressed these points, or, in the case of a patient with cancer, the true cause of the pain may have been withheld, and the patient will come expecting a cure and complete relief of symptoms.

2. When the pain is of the intermittent type, it is essential to ask the patient whether he has pain now. It is difficult to estimate the degree of relief of pain when there is nothing to relieve at the time of injection. In such instances the patient may have a means of bringing on his pain, and this should be encouraged before injection. Otherwise, it may be wise to put off the injection until another attack of pain begins.

In nervous and excitable patients who tolerate pain poorly, the injections may have to be carried out with the patient under light thiopental sodium (pentothal sodium®) or gas anesthesia, but usually a more reliable estimate of results can be made with the patient awake.

Before the block is begun, the patient's confidence and cooperation should be enlisted further by a frank discussion of what you are going to do, how much it will hurt, and what possible after effects he may experience. Most patients fear being stuck with needles, but the majority will attempt to cooperate if they are told what to expect. They also should be told that the first injection is mainly for diagnosis and that when the effect of the local anesthetic wears off their pain probably will return.

During the injection one should attempt on inserting the needles to obtain paresthesias which are similar to the patient's old pain. Nevertheless, the patient should not be subjected to a prolonged period of painful needle sticks merely to obtain paresthesias. In fact, the use of roentgenograms after the needles are in place and before the injection is made has almost obviated the necessity of obtaining paresthesias, unless they can be produced on the first two or three tries.

Nothing has been of more value toward insuring accurate results in these cases than routinely checking the position of the needles by roentgenologic methods. The most experienced regional anesthesiologists have found that needles they thought were correctly placed were often in gross malposition.

When the injection is completed, the patient should be allowed to rest quietly for 15 to 30 min., his attention being diverted, if possible, from his pain or the effects of the injection. At the end of this time he may be questioned as to results. If partial relief has been obtained, a further important question should be asked, namely, whether he would be satisfied if this degree of relief could be made permanent. This question should be repeated two or more times to make sure that the patient is either satisfied or dissatisfied with the results. His answer will dictate what the type of permanent treatment should be.

Certain types of pain seem to be more amenable to treatment than others. The pain of acute pancreatitis can usually be well controlled by splanchnic block, but the results are not nearly so satisfactory in pain associated with the gallbladder, stomach, and duodenum.

Among the blocks that are particularly efficacious are caudal block for pain due to pelvic cancer, bilateral alcohol block of the stellate ganglion for anginal pain, and blocking of the appropriate divisions of the fifth cranial nerve for trigeminal neuralgia. Usually good candidates for physical therapy present favorable cases for sympathetic block, since in these patients the two methods of treatment aid each other. In a similar way, the combination of therapeutic block with suitable psychotherapy and suggestion is valuable in certain types of neurotic patients.

In some patients nerve blocking seems to be contraindicated, for example, psychotic patients who have had multiple operations and certain injuries of the brachial plexus. Patients with traumatic avulsion of nerves can seldom be cured except by chordotomy. Patients with a phantom limb can occasionally be cured by sympathetic block. Patients who have had pain over prolonged periods, controlled by opiates or narcotics, or who have resorted to barbiturates for sleep and rest present very difficult problems. It is doubtful that any block will give them the comfort they look for until their addiction problem has been resolved. Unless one is convinced that this type of patient is thinking sanely, therapeutic block will be most unsatisfactory.

At the present time there is a relatively small percentage of patients with painful syndromes who can be given permanent or semipermanent relief. The fact that we are helping many patients who received little or no help in the past is encouraging. We can do still better if we apply ourselves to this important field. Certainly our results will be better when we have an agent that will produce a prolonged action without too many deleterious side effects. The longer-acting local anesthetic agents have not supplied the answer, nor has alcohol or the ammonium salts in benzyl alcohol.

A good result seems to make a dozen bad ones worthwhile. I recall a patient, a railroad roundhouse foreman, who had a small painful area in the chest wall which affected his sleep, work, personality, and livelihood. He had had it for three years and was most discouraged. He did not appear to be neurotic, but this small area of pain was coloring his whole life. The cause of his pain was not obvious, but for diagnosis I blocked the area involved. He obtained immediate relief and was dismissed when he was pain-free for 48 hr. After three months he wrote me that his pain had not returned and that he could put in a comfortable day's work for the first time in three years.

I do not yet know the origin or basis for this man's pain. The block therapy in his case was more or less a stab in the dark, but it produced results. In a neurotic patient who interprets even pressure as pain, this type of therapy probably would not have worked.

In conclusion, I should say that diagnostic block in suitable cases will give us much information toward either curing or alleviating pain, and, in addition, therapeutic block will make many miserable patients comfortable and give them a new outlook on life.

PONTOCAINE® SOLUTIONS FOR REGIONAL ANALGESIA OTHER THAN SPINAL AND EPIDURAL BLOCK

AN ANALYSIS OF 2,500 CASES

Daniel C. Moore, M.D., Seattle

Nerve block and local infiltration analgesia is often one of the important parts of a doctor's armamentarium. For years procaine hydrochloride (novocain®) has been the standard local anesthetic agent in most hospitals throughout the country. It meets Labat's requirements of a desirable local anesthetic agent:[1] (1) ease of sterilization; (2) ready and complete solubility in cold isotonic salt solutions in such concentrations as actually are used for induction of regional analgesia; (3) rapid and complete absorption locally, leaving no traces of its passage at the site of injection; (4) low toxicity, both when used in weak solutions and in such doses as are sufficient to produce surgical anesthesia; (5) ability to produce rapid onset of anesthesia; (6) one that is not decomposed by addition of a vasopressor, and (7) one that is not irritating to the tissue. Deaths have occurred during the use of procaine, but, since the acceptable approved agent was employed, a general feeling of opposition to its continued use was not aroused. One of the objections to procaine is the fact that the analgesia produced is relatively short, i. e., three-fourths to one and one-half hours. Therefore, in spite of establishing a satisfactory regional block, it often dissipates itself before surgery is completed. This is annoying to both doctor and patient, and consequently many procedures are performed under general anesthesia, in spite of the fact that local analgesia

Tetracaine (pontocaine®) hydrochloride furnished through the courtesy of Winthrop-Stearns, Inc.

Read before the Section on Anesthesiology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

[1] Labat, G.: Regional Anesthesia, London and Philadelphia, W. B. Saunders Company, 1930.

otherwise is preferred. Therefore, for the past few years we, as well as other anesthesiologists, have been interested in finding a drug with a low toxicity and a prolonged duration that might be employed routinely for nerve block and local infiltration analgesia.

TABLE 1.—*Comparative Total Intravenous Dose of Local Anesthetic in Cats*

	Average Fatal Dose, Mg./Kg.	Ratio Compared with Procaine	Equivalent Dosage Ratio	Corrected Toxicity Ratio Compared with Procaine
Procaine (novocaine®).....	49.6	1.0	1.00	1.00
Piperocaine (metycaine®) hydrochloride	28.8	1.7	0.80	1.36
Tetracaine	8.6	5.8	0.10	0.58
Dibucaine (nupercaine®) hydrochloride	3.5	14.2	0.05	0.71

A local anesthetic agent with a prolonged duration of action offers the following advantages:

1. It permits regional analgesia to be carried out with finesse and minimal trauma, since rapid completion of the block is not necessary to conserve analgesia. This is especially true in extensive block procedures.
2. The anesthesiologist can give valuable instruction to his pupils. This is important, since it will increase the number of men who can skilfully execute regional procedures.
3. Local anesthesia may be used when indicated for the benefit of the patient, in spite of the necessity for slow, careful dissection. This is especially true in cases of diabetes and hypertension.
4. The operating surgeon is at ease, since he knows that the surgical analgesia will be adequate for five to six hours.
5. The surgical schedule may be changed suddenly for an emergency, even if the block has been executed. This is a definite advantage to the patient, since a second block will not have to be performed before operation, even if the emergency procedure should require two or three hours.
6. Postoperative analgesia is prolonged, thus reducing the necessity for large amounts of opiates during the immediate postoperative period. This is important because, if the patient is free from pain and not under the influence of opiates, he will follow the "stir-up" regimen immediately.
7. The block may be carried out at the convenience of the anesthesiologist, a factor of obvious importance in private practice.

During the past few years an increasing number of articles have appeared on the use of tetracaine (pontocaine®), indicating that it might be the answer to the search for a local anesthetic agent with Labat's qualifications plus a prolonged duration of action.[2] It has been shown in Novak's table of comparison [3] that, although milligram for milligram tetracaine is more toxic than procaine, it is effective when employed in solutions one-tenth as strong as effective procaine solutions (table 1). Therefore, effective solutions of tetracaine are actually less toxic than comparable procaine solutions.

A previous paper based on the first 1,004 cases in this series has been published,[2d] and the growing interest in the use of tetracaine for nerve block and local infiltration prompted this reevaluation of our clinical study on this subject.

PROCEDURE

The procedure employed was the same as that reported in the first 1,004 cases and briefly consisted of the following salient points.[2d] Patients of all ages, physical status, and operative risk for whom nerve blocks were advocated received tetracaine without screening (table 2). Tetracaine (pontocaine hydrochloride "niphanoid"®) crystals were used in all cases and mixed with isotonic sodium chloride solution to the desired concentration and volumes. Each operation was counted as a case, not each individual block—i. e., a block for a radical mastectomy was counted as one anesthetic procedure, not three, although it includes a brachial block, an intercostal block, and a superficial cervical block. Premedication varied from none to heavy sedation with barbiturates, opiates, and the belladonna derivatives. Epinephrine (adrenalin®), suprarenin,® and phenylephrine (neo-synephrine®) hydrochloride in amounts from 0.2 cc. to 0.5 cc. were employed in the study, regardless of the volume of solution. All patients received the calculated number of milligrams of tetracaine and cubic centimeters of vasopressor drugs. For example, if we mixed 90 cc. of 0.15% tetracaine with 0.2 cc. of epinephrine (1:1,000) for a brachial block, the patient received the total amount, even though paresthesias were obtained and a satisfactory block would have resulted after 40 to 50 cc. of the solution was administered. This method was selected in order that the patient might receive a relatively large number of milligrams of tetracaine and a calculated number of cubic centimeters of vasopressor drug.

RESULTS AND DISCUSSION

In the 2,500 procedures 39 different types of regional blocks were performed (table 3). There were 1,352 males and 1,148 females in the series of patients. Many of the patients having therapeutic and diagnostic blocks required more than one block, which explains the discrepancy between the number of patients and the number of cases. A large variety of operations in various parts of the body were performed (table 4).

Tetracaine (pontocaine hydrochloride "niphanoid"®) crystals are readily soluble in isotonic sodium chloride solution and did not produce irritation or slough of the skin. It was rapidly dissipated from the tissue, and skin wheals and tumefactions disappeared in one-half to one hour.

Solutions of tetracaine appear to be stable and retain their anesthetic properties for at least 48 hr. Our solutions were not allowed to stand for a longer period, and, at present, the solution is mixed just before the block is performed. In the early part of the series one to two days' supply was prepared, sterile Erlenmeyer flasks being used as mixing receptacles. These flasks often stood 24 to 48 hr. before the solution was used, and satisfactory anesthesia was obtained. Tetracaine solutions can be boiled repeatedly without deterioration but are rendered inactive by alkalis. Most glass receptacles are highly alkaline; if tetracaine solutions are prepared in such containers, the possibility of having a chemically altered solution must be considered. This is the reason that stainless steel mixing receptacles are used.

A vasopressor agent may be used in tetracaine solutions without causing decomposition. It is not necessary to make the tetracaine solutions potent anesthetic agents. This was found to be true because the solutions that were given to 17% of the patients who had therapeutic and diagnostic blocks and to diabetic patients did not contain a vasopressor drug. The vasopressor drug seemed to have little influence on the duration of anesthesia or postoperative analgesia (table 5). This was especially true in the case of the diabetic patient who received no vasopressor and whose anesthesia and postoperative analgesia times were comparable to those of patients in whom a pressor agent was employed.

Blood pressure is unaffected by the tetracaine solution, except when a vasopressor is used, and in such cases a transient rise in blood pressure with a fall to normal in 30 to 40 min. may occur. Pulse rate and respirations are unaffected.

Massive amounts of tetracaine hydrochloride in milligrams and large volumes of solution were used. It can be seen from table 6 that, although percentages varied to meet various volume demands in extensive block procedures, the average number of milligrams of tetracaine hydrochloride employed in each block was fairly constant. The minimal dosages used were not included in this chart because we were trying to determine whether large doses of tetracaine were safe. All the concentrations of tetracaine shown in table 6 produced effective operating analgesia. The higher percentages were used merely to shorten the time period between completion of the block and onset of surgical anesthesia. The establishment of analgesia with tetracaine depended entirely on the percentage employed and the accuracy of the placement. Concentrations of 0.1, 0.15, 0.2, and 0.25% require 30 min. or longer to assure a workable block. Concentrations of 0.3 to 0.5% produce anesthesia in less than 20 min. (table 7).

Probably the outstanding property of tetracaine hydrochloride is its prolonged action. It gives a minimum of five hours' operating time, as proved by actual operations. We have done gastric and pancreatic resections, using deep splanchnic and intercostal blocks for relaxation with 2 l. of nitrous oxide and 1 l. of oxygen a minute for analgesia. Also, blocks for two-hour operations have been performed three hours before the surgical procedure was started, and anesthesia of the part was still present at completion of the operation. Table 4 shows actual operating and anesthesia times of various surgical procedures.

Total	1,583				

The exact maximum time tetracaine effect will last has not been determined. Skin anesthesia has been present for eight to nine hours, but this does not indicate that the deep tissues could be manipulated (table 7).

Postoperative analgesia is indeed striking and gratifying to the patient, surgeon, and anesthesiologist. Analgesia may last for nine hours and definitely permits early institution of the "stir-up" regimen (table 7). The amount of opiates required postoperatively is greatly reduced. In many cases, especially when casts are applied, no sedation is required. In upper abdominal surgery muscle spasm is greatly reduced, and this, in turn, reduces the amount of opiates necessary. It is not uncommon for a patient to require less than a total of 1 to 1½ grains of morphine sulfate after gastric resection or cholecystectomy.

TABLE 5.—*Three Vasopressors Used*

No. of Cases		No. of Cc.	Reactions	Length of Time of Operative Analgesia, Hr.
1,688	Epinephrine	0.3	2	5-6
347	Phenylephrine	0.5	1	5-6
40	Suprarenin®	0.5	4	5-6
425	No vasopressor	...	..	5-6

We, as well as other workers, were impressed with the fact that the nervousness, excitement, and restlessness that often accompany procaine injections were noticeably absent when tetracaine was infiltrated.

There have been no palsies or areas of prolonged anesthesia. Five complications occurred other than the reactions later described. Three of these were pneumothoraxes and two were atelectases, but these could not be attributed to the tetracaine.

There were two reactions to epinephrine (adrenalin®) (1:1,000) in 1,788 cases. One reaction to 1% phenylephrine (neosynephrine®) occurred in 357 cases and four reactions to suprarenin® in 40 cases (table 5). This led to the suspension of use of suprarenin® early in the series. The one phenylephrine reaction occurred in a 44-year-old white woman who had a lumbar sympathetic block of 40 cc. of 0.25% tetracaine solution and 0.5 cc. of phenylephrine for thrombophlebitis. Before the procedure her blood pressure was 130 mm. systolic and 86 mm. diastolic, her pulse rate was 76, and her respiration rate was 18. She had received no premedication. Ten minutes following completion of the block she became nauseated and nervous, and felt that it was difficult to breathe. The blood pressure rose to 190 mm. systolic and 100 mm. diastolic, her pulse rate was 100, and her respiration rate was 30. In 30 min. she became quiet, and her blood pressure, pulse rate, and respiration rate approached the preanesthetic level. It could be argued justly that this was a mild tetracaine reaction, except for the subsequent course. The next day another lumbar sympathetic block was performed. The same amount and percentage of tetracaine was used, but the phenylephrine was omitted. The patient's course was uneventful during this therapeutic block. The two epinephrine and four suprarenin® reactions followed the same pattern as in this case.

TABLE 6.—*Percentage Comparisons*

Tetracaine, Per Cent	No. of Cases	Dosage Used				Reactions to Tetracaine		Reactions to Vasopressor	
		Max. Cc.	Max. Mg.	Aver. Cc.	Aver. Mg.	Min	Sev.	Min.	Sev.
0.1	180	250	250	150	150	0	0	0	0
0.15	738	110	165	85	125	9	3	0	4
0.20	126	100	200	60	125	0	0	0	0
0.25	914	100	250	50	125	0	1	0	3
0.3	162	40	120	40	100	0	0	0	0
0.4	19	30	120	30	120	0	0	0	0
0.5	61	40	200	10	50	0	1	0	0

In 2,500 cases there were 14 reactions to tetracaine; these reactions were classified as minimal or severe.

Minimal Reactions.—Seven cases characterized by drowsiness only occurred during superficial and deep cervical block for thyroidectomies. There was no change in the blood pressure or the pulse. In each of these blocks 90 cc. of 0.15% tetracaine solution with 0.3 cc. of 1% phenylephrine and 150 turbidity-reducing units of hyaluronidase was employed. No treatment was given, and the drowsiness passed in five to 20 min.

Two cases characterized by irregular heart rates corrected themselves without treatment in 10 min. One occurred after a brachial block and the other after a sciatic and femoral block. In these cases 90 cc. of a 0.15% tetracaine hydrochloride solution with 0.3 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase was employed.

Severe Reactions CASE 1.—A well-developed and well-nourished white man had been hospitalized for tic douloureux, and a gasserian ganglion block was being executed. The needle was placed, and aspiration yielded no blood or spinal fluid. The open needle was then allowed to stay in place for one minute to be sure the dura or a blood sinus had not been entered. Two cubic centimeters of a 0.5% solution of tetracaine with 0.3 cc. of 1% phenylephrine was injected. The blood pressure was 130 mm. of mercury systolic and 70 mm. of mercury diastolic, the pulse rate was 80, and the respiration rate 18. Within one minute the patient began to feel dizzy and complained of being faint. He lost consciousness and had some twitching movements of his hands and feet but no generalized convulsion. The blood pressure rose, as did the pulse rate, and respirations became shallow and rapid. Cyanosis became more pronounced, and respirations ceased. At this point intubation was performed, and artificial respiration was instituted. The blood pressure had risen to 200 mm. of mercury systolic and 110 mm. of mercury diastolic, and the pulse rate was 130, but of fair quality. Artificial respiration was continued for 25 min. before the patient gradually took over his own respirations and regained consciousness. As soon as artificial respiration was instituted, the blood pressure and pulse rate gradually returned to normal. No barbiturate was used intravenously. Whether or not this was a subdural, intra-arterial, or intravenous injection is open to argument. The reaction was not due to a sensitivity to tetracaine or phenylephrine solutions, as previous and subsequent injections with tetracaine-phenylephrine solutions had been administered to this patient without reaction.

TABLE 7.—*Operative and Postoperative Analgesia*

Tetracaine Per Cent	Time for Analgesia to Establish, Min.	Duration of Operative Analgesia, Hr.	Postoperative Analgesia, Hr.
0.1	30-45	4½-6	4-9
0.15	30-45	5-6	4-9
0.20	30-45	5-6	4-9
0.25	20-30	5-6	4-9
0.3	15-25	5-6	4-9
0.4	10-15	5-6	4-9
0.5	10-15	5-6	4-9

CASE 2.—A 68-year-old white woman had been operated upon uneventfully for an acute gallbladder condition under intercostal deep splanchnic block employing 150 cc. of 0.1% tetracaine solution with 0.4 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. She was known to be a cardiac and had a grossly irregular pulse before operation. The first day postoperatively a right therapeutic intercostal block was administered, employing 50 cc. of 0.25% tetracaine solution with 0.2 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. Five minutes after the completion of the block she became irrational; her blood pressure dropped from 124 mm. of mercury systolic and 86 mm. of mercury diastolic to 86 mm. of mercury systolic and 42 mm. of mercury diastolic; her pulse rate was weak but retained the same irregularity as before the block, and she began to perspire and feel clammy. Apnea or convulsions did not occur. Oxygen was administered for 15 min., and the patient recovered. She left the hospital in the usual time.

CASE 3.—A 58-year-old white woman had an uneventful cholecystectomy under intercostal deep splanchnic block employing 150 cc. of 0.1% tetracaine solution with 0.4 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. Postoperatively she had two right therapeutic intercostal blocks, carried out uneventfully each time with 50 cc. of 0.25% tetracaine with 0.3 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. An elective subtotal thyroidectomy was scheduled, and the patient received a superficial and deep cervical block, employing 90 cc. of a 0.15% tetracaine solution with 0.3 cc. of 1% phenylephrine and 150 turbidity-reducing units of hyaluronidase. Ten minutes after completion of the block she became cyanotic and had a convulsion lasting 20 sec. Oxygen was administered under pressure, and she responded without further treatment. Surgery was performed, and her postoperative course was uneventful.

Case 4.—An 82-year-old white woman was to have a thyroidectomy for toxic adenoma under superficial and deep cervical block. The block was administered using 0.15% tetracaine solution with 0.3 cc. of 1% phenylephrine and 150 turbidity-reducing units of hyaluronidase. Five minutes after completion of the block respirations became shallow and ceased. Artificial respirations by oral airway and mask were performed. Her pulse rate increased from 92 to 120 but was of good quality. Her blood pressure rose from 150 mm. of mercury systolic and 90 mm. of mercury diastolic to 200 mm. of mercury systolic and 120 mm. of mercury diastolic. After five minutes of oxygen therapy shallow respirations resumed, and in 10 min. respirations were normal, and blood pressure and pulse rate had returned to the preanesthetic level. The operation was uneventful, as was the postoperative period.

Case 5.—A 55-year-old white man who previously had had a gastric resection for duodenal ulcer reentered the hospital complaining of pain and a dumping syndrome. He was deformed severely from arthritis, necessitating performance of the gastric resection with the patient in the sitting position. At that time he received endotracheally an anesthetic of nitrous oxide, oxygen, and ether. After this operation he received a bilateral therapeutic intercostal block, using 60 cc. of 0.2% tetracaine solution with 0.3 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. Immediately after the block his blood pressure fell from 90 mm. of mercury systolic and 50 mm. of mercury diastolic to 60 mm. of mercury systolic and 0 mm. of mercury diastolic, and he became cold and clammy but did not lose consciousness or become apneic. Oxygen was administered, and the patient's condition was satisfactory in 30 min. His recovery from the operation was uneventful. At this readmission the surgeon, feeling that a bilateral thoracic sympathetic block of the fifth through the 12th thoracic nerve segment would correct the dumping syndrome and ease pancreatic pain, requested our opinion. His first two requests were refused on the basis of the patient's severe arthritis with poor landmarks and his previous reactions to a block procedure. However, after the third request, the block was attempted, employing 90 cc. of a 0.15% tetracaine solution with 0.3 cc. of epinephrine (1:1,000) and 150 turbidity-reducing units of hyaluronidase. No sedation was given, but after severe pain occurred on the placing of the first two needles, 0.6% thiopental (pentothal®) sodium was given to the point of analgesia. At the completion of the block the patient ceased breathing. This was 30 min. after the block had been started. The patient's blood pressure was 110 mm. of mercury systolic and 70 mm. of mercury diastolic, his pulse rate was 76, and his respiration rate 18 at the beginning of the procedure. A quick check revealed no pressure or pulse. Oxygen was administered endotracheally, and other resuscitation drugs such as atropine and epinephrine were given intravenously. Cardiac massage was not attempted as the facilities and personnel were inadequate. The patient was pronounced dead one hour and fifteen minutes after the cessation of breathing. Postmortem revealed nothing. We feel this death was caused by faulty injection, probably subdural, although the pathologist could find no puncture of the dura. Of course, the possibility of a sensitivity to the local anesthetic solution must be considered. Nevertheless, I am reluctant to condemn the anesthetic solution in view of the patient's severe deformity.

It is interesting to note that when tetracaine solutions without hyaluronidase were employed, only one reaction was observed in spite of the relatively large amounts of tetracaine employed. Hyaluronidase, which is now considered the spreading factor by Duran-Reynals and McClean, was used in 1,000 of the above cases.[4] One would expect to see more reactions in these cases because the greater diffusion of the local anesthetic solution results in a greater absorption of the tetracaine. In the series of cases in which hyaluronidase was added, the same amount and concentration of tetracaine solutions were employed for the block in question as when hyaluronidase was omitted.

Reactions from tetracaine solutions per se, used for regional procedures other than subarachnoid block, epidural block, and topical analgesia, are infrequent, as shown by the recent available literature.[2]

The reactions which were observed during the series in which hyaluronidase was added gave us some insight as to the type of toxic reactions one might expect in the use of tetracaine, the blocks in which they are most likely to occur, and what treatment should be instituted. Nine of the reactions occurred during superficial and deep cervical blocks. This could well be anticipated because of the high vascularity of the neck with either rapid absorption or possible intravascular injection. The remaining five reactions occurred from injections in various regions of the body. All the reactions occurred usually five to 10 min. after the block was completed, which indicates that careful, not casual, observations should follow a tetracaine block for at least 15 min. The reactions were not heralded by restlessness, apprehension, and dizziness, which are often a warning when procaine is employed. On the contrary, these patients become drowsy; respirations were first shallow and then absent. In only one case were convulsions severe. In two of the severe reactions the blood pressure declined, and the pulse rate became rapid and weak. This would seem to indicate that tetracaine depresses cardiac activity, and perhaps in the presence of cardiac damage it is best avoided. On the other hand, patients who have had coronary occlusions and other heart insufficiencies, as shown by electrocardiogram, have tolerated tetracaine blocks without any difficulty. Also, because of this evidence of cardiac depression, perhaps intravenous or intracardiac administration of epinephrine may have been indicated in the case in which the patient died. However, to date we have not looked fondly upon its use. It would appear from the present toxic reactions that tetracaine tends to depress first the respiratory center and that deaths, when they occur, may be respiratory in nature. To date we have administered only oxygen to these patients by mask, maintaining a clear airway with an oral airway or an endotracheal tube. We have seen but one severe convulsion, and this stopped before a barbiturate could be started intravenously. However, had it continued, we

McClean, D.: Studies on Diffusing Factors: Methods of Assay of Hyaluronidase and Their Correlation with Skin Diffusing Activity, Biochem. J. 37: 169, 1943.

would have used small doses (50 to 100 mg.) of thiopental to control the convulsion. We have not used vasopressors to maintain a blood pressure, as the blood pressure has not fallen to a dangerous level, except in the case in which the patient died. We feel that this death was caused by a faulty injection, probably subdural, with a block of the cardiac accelerator fibers and cardiac arrest. Had cardiac massage been feasible in this case, it would have been attempted; however, by the time it could have been instituted the critical period of three to five minutes would have been exceeded.

SUMMARY

Tetracaine (pontocaine®) has many advantages for regional procedures and may be the answer to our search for a more satisfactory local agent. It has all the requirements listed by Labat for the ideal agent, with the exception of rapid onset of analgesia when very weak solutions are used. This disadvantage is easily offset by its prolonged anesthetic action. Tetracaine's retarded onset of analgesia is noticeable only in nerve block or field block analgesia, and, even then, this varies with the concentration of the solution and accuracy of placement. When tetracaine is used for intradermal and subcutaneous infiltration, almost instantaneous analgesia is produced.

This series of cases, as well as others reported, indicates that tetracaine in large amounts is a safe local anesthetic agent for nerve block or infiltration procedures. It also must be pointed out that in most cases every block in this series could have been performed adequately with approximately one-half of the tetracaine dosage employed. However, the large dosage was used to determine the safety of tetracaine.

Fourteen reactions to tetracaine occurred in 2,500 cases. Tetracaine reactions are not heralded by restlessness, nervousness, and dizziness. They are often unheralded and usually occur five to 15 min. after the completion of the block. They are characterized by drowsiness, shallow respirations, and apnea. Blood pressure and pulse rate usually do not vary. Careful observation of these patients, as required with any other anesthetic procedure, is essential. Reactions to tetracaine were combated with oxygen therapy only. However, if the blood pressure falls, it should be supported with vasoconstrictor agents, and only if convulsions are present and sustained or repeated should a barbiturate be administered intravenously. Should cardiac arrest occur, cardiac massage, if at all feasible, should be considered. There was one death which we feel was caused by faulty technique and poor selection, not to the drug in question.

Vasoconstrictor agents do not alter the anesthesia produced by tetracaine and may be omitted from the solution at any time. Reactions from vasoconstrictor agents are treated in the usual manner, i. e., oxygen therapy and reassurance of the patient and, if the blood pressure becomes alarmingly high, administration of sedatives, preferably 50 to 300 mg. of thiopental intravenously.

Tetracaine gives a minimum of five hours of anesthesia when used for nerve block and local infiltration.

Prolongation of therapeutic and diagnostic procedures is obviously of great importance and advantage; therefore, tetracaine may be the drug of choice for this work.

Postoperative analgesia lasts from four to nine hours. This is of utmost importance in reducing postoperative complications and instituting early ambulation.

There were no nerve palsies or areas of prolonged anesthesia in this series of cases.

CONCLUSIONS

The results of 2,500 regional analgesia procedures other than epidural or subarachnoid block are presented.

This series of cases shows that tetracaine is a safe, desirable, local anesthetic agent when it is used in dilute solutions which are effective in producing adequate analgesia.

Patients who have tetracaine reactions can be resuscitated.

Further study with tetracaine should be undertaken in order that a larger number of reports from various investigators may be available.

ABSTRACT OF DISCUSSION

On Papers by Drs. Adams, Pender and Pugh, and Moore

Dr. John J. Bonica, Tacoma, Wash.: The excellent results obtained in some patients who have excruciating pain due to malignancy, tic douloureux, pancreatitis, renal colic, causalgiac states, and many other disorders are very gratifying and often cause a great deal of enthusiasm on the part of both the referring practitioner and the regional anesthesiologist. It is important that these results do not cause us to become overenthusiastic, for unless we avoid the promiscuous use of diagnostic and therapeutic nerve blocks, we will become discouraged. It is important to realize the limitations inherent in this method and the great deal of time and patience entailed in its proper administration. One must be willing to devote much more time to these patients than the average clinician can afford, and perhaps the fact that the anesthesiologist is able and willing to spend this much time has been one of the most important reasons why his medical confreres have relinquished this function to him. It is most important, as Dr. Adams has emphasized, that the patients are carefully selected. If nerve blocking is the procedure of choice, it is important that all those concerned are made to realize that the earlier the block, the better the therapeutic results. In order to obtain optimum results in those patients who have been selected as suitable, the administrator must be thoroughly familiar with the present concepts of pain mechanisms and the anatomic, physiopathological, and psychological factors involved in the various disease conditions. One must be expertly familiar with the technic of selectively blocking the involved nerve pathways. Constant practice, which can be done on fresh cadavers just prior to or during postmortem examinations, and frequent use of regional procedures for surgical anesthesia will improve the dexterity of the regional anesthesiologist. Haphazard injection of nerves must be avoided or nerve blocking will be of little value. The results must be evaluated objectively by means of temperature and sudomotor studies, photographs, and x-rays. It is of the utmost importance that accurate detailed records are kept so that the results may be analyzed later, and conclusions derived therefrom. In the past five years two factors have contributed to better results in our cases. One has been the use of roentgenograms to aid in the proper placement of needles. Dr. Pender's and Dr. Pugh's timely paper expresses our views on this subject, and I hope it will stimulate those who have not availed themselves of this excellent aid to do so in the future. We have found x-rays of inestimable value in obtaining a clearer concept of nerve blocking and in teaching regional procedures to residents, particularly in blocks of the gasserian ganglion, of the divisions of the trigeminal nerve, and in blocks of the glossopharyngeal, vagus, and accessory cranial nerves. The other factor which has contributed in bettering our results has been the use of dilute solutions of tetracaine because its effects much longer blocks than procaine. To date we have employed and thoroughly investigated tetracaine in nearly 5,000 regional procedures other than spinal block and have arrived at the same conclusions as Dr. Moore has just presented.

Dr. J. W. Winter, San Antonio, Tex.: Diagnostic, prognostic and therapeutic blocks present a perplexing problem. A careful study of each patient before starting a block is essential. Overlooking metastic carcinoma, syphilis, or other degenerative diseases of the central nervous system, when they are the causative factor of pain, paresis, or circulatory disturbances, can be most embarrassing. Knowledge, experience, and diligent study, as well as careful technical execution of nerve blocks, will improve the number of satisfactory results. For best results treatment of intractable pain should be started as early as possible. Procrastination also tends to lead to loss of personality and addiction to narcotics, which reduces the chance of cure to almost zero. Alcohol should be reserved for blocking the trigeminal and sympathetic nerves and for intraspinal injection. Its use on peripheral nerves seems to be because of inexperience or the acquisition of some skill we do not possess. We find many cases in which pain has been alleviated with ammonium salts injected intraspinally or peripherally when it is of somatic nerve origin, but we cannot predict the chance of cure in a given case. Our results have improved since we have increased the concentration for peripheral nerves. Proper placing of the needles for any type of nerve block is necessary for success. Near hits frequently will be sufficient for successful analgesia if large quantities of local anesthetic agents are used. Direct hits are demanded for results when the use of smaller quantities is necessary, as indicated when an anesthetic agent is being used prognostically or for therapeutic alcohol blocks. X-ray is a poor substitute for knowledge and training in regional anesthesia. In fact, there are many blocks in which the unskilled and unsuspecting occasional regional anesthetist, falsely comforted by the assistance of x-ray, might cause disaster. If x-ray is used as a supplementary aid to blocks performed by a well-trained regional anesthetist, increased accuracy and better results can be expected. Frequently we desire longer-acting local anesthetic agents than procaine hydrochloride. It often wears off before maximum warming of an extremity occurs when it is used for sympathetic blocking in a room with controlled temperature, whether it be used on the ganglia or intraspinally. Tetracaine takes effect quickly enough to be used as a spinal agent, but it is rather slow as a regional agent. Therefore, for major surgery we usually use 1 Gm. of piperocaine (metycaine®) hydrochloride or procaine with 60 mg. of tetracaine added. Length of action is from three to five hours. For surgery lasting longer than three hours it seems logical to use tetracaine alone as the local anesthetic agent. Untoward reactions from tetracaine rarely occur, but when they do they last longer than those from procaine or piperocaine. It is advocated that every one using these agents in the office or hospital keep a short-acting barbiturate and oxygen nearby for possible resuscitation.

Dr. Richard H. Barrett, Hanover, N. H.: I am happy to hear Dr. Adams state that the anesthesiologist of today performs a great variety of functions in addition to clinical anesthesia. I will go further; the anesthesiologist of today is the *general practitioner* of specialized medicine. The reason we have been successful in a lot of this work is that we have taken time to listen to these patients' stories. Many patients have been diagnosed as being "neurotic." Anyone having a prolonged pain has good basis for his neurosis. One question asked frequently is, "How long will a block last?" The effect of a local anesthetic, even tetracaine, lasts not longer than five to, possibly, nine hours, and procaine lasts only three or four hours. The beneficial effect of block therapy is probably owing to its effect upon the sympathetic rather than on the somatic nervous system. If alcohol is used, it must be dehydrated ("absolute") and sterile (spores live in nonsterile alcohol). The use of roentgenograms in doing diagnostic and therapeutic blocks is ideal. There is a question of their necessity in connection with therapeutic blocks, per se, because of the expense involved in repeated procedures, and, as mentioned by Dr. Pender, many blocks can be evaluated adequately upon their therapeutic effect. Internists and surgeons should be educated to tell the patient that he may need a series of blocks, no just *a* block, especially after he has received innumerable x-ray and diathermy treatments and alcohol block is not contemplated. The rational for using x-rays for the proper placement of block needles is comparable with its use for the proper placement of pins in bone-nailing procedures. The use of alcohol in nerve blocks should be a *last* resort, or a substitute for refused surgery, never a *first* resort. The practice of putting alcohol in the sciatic nerve usually is contraindicated. Nine times out of ten so-called "sciatica" is a *symptom, not a disease*, and should be treated as such. The sympathetic nervous system is a dominant factor in pain; except for direct nerve trauma, ischemia, or localized hypoxia, it is probably the basis of most pain. Relieve the ischemia, and you relieve the pain. Nerve tissue dislikes ischemia. It makes this fact known via somatic or sympathetic nerves. We should attempt to reestablish the normal status quo, that is, normally functioning nervous tissue and—pardon the expression—avoid the use of anesthetic cosmetics, if we consider only the somatic system. Procaine has been beneficial through the years in blocking sympathetic nerves, allowing vascular release, counteracting ischemia and associated hypoxia, and allowing nervous tissue to function again normally. Only a few minutes or hours of anesthesia may be necessary to stop a vicious cycle. This can be done by repeated blocks. One problem sometimes encountered is that of a surgeon wanting to do an operation under local anesthesia because of the poor-risk patient, believing that even block anesthesia may cause more trauma. I have seen surgeons operate on a "poor-risk" under so-called infiltration anesthesia and use almost a bucketful of procaine, believing this is causing less trauma or less toxic effect to the patient than block anesthesia. It is almost akin to a procaine *bubble bath*.

Dr. John W. Pender, Rochester, Minn.: Dr. Lundy has suggested that I mention the technique which we have found useful in the injection of nerves with dehydrated ("absolute") alcohol. The technique has been termed "spot wetting," to rhyme with "spot welding" in other types of endeavor. If one intends to inject a nerve with, say, 2 cc. of dehydrated alcohol, the technique is to inject 0.5 cc. at a time, rather than the whole amount, waiting for intervals of one to two minutes between injections. That is an attempt to confine the area in which the alcohol exerts its effect to the smallest diameter. In this way one can block only the nerves that are intended to be blocked, and not have the alcohol spread to other nerves where it may produce undesirable effects.

Narcotic Effect of Morphine.—After a few minutes there is an undefined feeling of general comfort. The mental faculties are agreeably stimulated, the brain seems more active and without any sense of oppression. Fantastic lights and glimmerings appear before the eyes. There is a desire to remain undisturbed, the slightest attempt at movement is a trouble. Questions are only answered indefinitely; glimpses of indistinct, agreeable visions appear. All these pleasant feelings, however, are of short duration. The eyelids begin to droop, the individual who, in the previous enjoyment of comfortable respose, was disinclined to move his limbs is now unable to do so. Every impulse which emanates from the brain for that purpose passes off without effect. The whole body feels heavy like lead. This is the last thing noticed, and soon afterwards the individual sinks into a profound sleep.—K. Binz, M.D., Lectures on Pharmacology for Practitioners and Students, New Sydenham Society, London, vol. 1, 1895.

ROUTINE EXAMINATION OF THE OCULAR FUNDI AS AN AID IN MANAGEMENT OF TOXEMIAS OF PREGNANCY

Dan M. Gordon, M.D., New York

Since the retinal arterioles tend to mirror and parallel the arteriolar changes in other vital organs, routine ophthalmoscopy is essential in those pregnancies in which elevation of blood pressure or alterations in the renal and other studies indicate a possible deviation from the normal course of pregnancy.

A massive, and at times confusing, literature has arisen concerning the ocular findings in the toxemias of pregnancy; confusing because some authors have failed to differentiate between those changes in the ocular fundi that eventually occur in all patients with persistent hypertension and the ophthalmoscopic findings that occur purely by virtue of the existence of a toxic process in the course of pregnancy, with or without evidence of preceding cardiovascular-renal damage.

From an ophthalmoscopic point of view the patients with toxemia may be divided into two main groups: those with no evidence of prior vascular damage and those with such evidence. More simply stated, the question is one as to whether the pregnancy is complicated by hypertensive phenomena or whether the hypertension is in danger of becoming further complicated by the pregnancy.

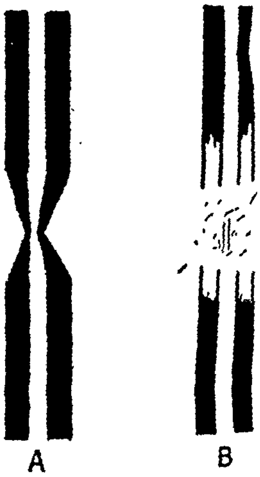
The first group may be subdivided into two subgroups: (1) women in whom the pregnancy has a toxic effect causing eyeground changes that may or may not recur with succeeding pregnancies and (2) women in whom a predisposition to cardiovascular-renal disease may be hypothesized and in whom the pregnancy acts as the mechanism that sets off a chain of events leading to permanent vascular damage.

In those women (the second group) who evince signs of an already impaired vascular system an apparently normal pregnancy may serve to increase the residual postpartum hypertension slightly or not at all; whereas the intervention of a toxemia may increase the hypertensive state, as determined by postpartum examinations.

RETINAL CHANGES SEEN DURING TOXEMIA

The first sign of impending circulatory difficulty, seen in the retina of the toxemic patient, is a narrowing of some or all the arteries. Normally, the nasal arteries are narrower than the temporal, and hence such a narrowing may first be seen on the nasal side of the disk. In the healthy eye the caliber of the arteries as compared with the accompanying veins is as 2:3. During the stage of narrowing this ratio may become 2:4 or even 1:4. In determining this ratio it is important to compare the artery with its accompanying vein at the same level. This is best done by observing the temporal vessels, close to the disk, before either the artery or the vein has bifurcated. For practical purposes the arteries in the retina may be considered as arterioles.

With the continuation of the toxemia a second stage, marked by localized spasms in one or more sites in one or more arterioles, is seen. These usually occur in the temporal arteries and usually fairly close to the disk. The affected vessel looks as though it has been pinched in one or more places. The spasm may be transient and may change sites frequently. The retina at the site of the spasm may be grayish or whitish or may look "wet." It is my feeling that prognostically this type of spasm, with accompanying local retinal changes, is worse than that that has no such changes. Some authors feel that the spasms may occur simultaneously with the onset of the vessel narrowings. It is true that one occasionally sees the spasms without any significantly appreciable narrowing of an accompanying vessel. In my experience this is as significant as spasm plus narrowing.



Purely schematic drawing of spasm, as seen ophthalmoscopically. *A* indicates a "pinched" artery; *B*, an appearance seen frequently, in which the "spastic" portion of the artery is practically invisible, with some edema at the site of the spasm.

If termination of the pregnancy takes place during the foregoing stages, permanent vascular damage is not apt to occur. Wagener[1] states that "as long as the lesions in the arterioles are definitely spastic [and not organic] if the condition of the patient is otherwise satisfactory it is safe to temporize." That statement does not completely coincide with an experience at the Lying-In Hospital (a unit of the New York Hospital), since my colleagues and I have seen at least one patient whose ocular fundi showed only generalized narrowing of the arterioles (without any localized spasms), and who lost her baby six weeks before term and two days before delivery. This patient's second pregnancy was uneventful, except for a blood pressure of 140/90. A cesarean section was safely performed about one week before term. It is quite probable that she would have had an uneventful delivery had she been permitted to go to term. We have seen fetal death occur during the stage of spasm without any evidence of progression of the retinal changes to the later stage of retinopathy (hemorrhages and/or transudates). The following cases are illustrative.

REPORT OF CASES

CASE 1.—M. L., aged 35, entered the Lying-In Hospital, a unit of the New York Hospital, on Oct. 16, 1946 in the twenty-eighth week of pregnancy. Her blood pressure was 140/90. Her eyegrounds were examined on October 17 and were reported as essentially normal fundi with the exception of some widening of the arterial "reflex stripes." On October 20 some narrowing of the peripheral vessels was noted. Her blood pressure was never re-

---

From the New York Hospital, Cornell University Medical College.

[1] Wagener, H. P.: Retinitis of Malignant Hyptertension, Tr. Am. Ophth. Soc. **21:** 348, 1927; Arterioles of the Retina in Toxemias of Pregnancy, J. A. M. A. **101:** 1380 (Oct. 28) 1933; Lesions of the Optic Nerve and Retina in Pregnancy, ibid. **103:** 1910 (Dec. 22) 1934.

corded as being over 148/110. The only significant finding in her general condition was a failure of the blood pressure to respond to bed rest and sedation. The fetal heart sounds were lost on November 4 and a stillborn infant delivered spontaneously on November 8. Two days later the patient's ocular fundi appeared normal.

She was readmitted March 16, 1948 about one week before term, with a blood pressure of 140/100. At that time her fundi exhibited slight widening of the arterial reflex stripes with no evidence of narrowing or spasm. Because of her age and prior experience it was deemed advisable to perform a cesarean section. This was done and a living 3,470 Gm. child delivered.

Case 2.—M. S. was seen in the Lying-In Hospital in 1946, when she had a 4½ month spontaneous abortion. At that time her blood pressure was 150/110. She was seen again in October 1947 with a history of having had her last menstrual period in July. She continued to be seen in the outpatient department, where she had a borderline blood pressure until Feb. 28, 1948, when her pressure was recorded at 170/110, which, it was felt, warranted admission to the hospital. It was thought that her fetus weighed in the neighborhood of 1,200 Gm.

She was seen by several members of the eye department of the New York Hospital on March 5, when her arterioles were found to be narrowed, with several areas of spasm in the temporal arteries. The arteriovenous ratio was 1: 2, and the arteries were thin and transparent in appearance. On March 15 it was felt that the generalized narrowing of the arteries had increased. The next day we felt that the spasm was decreasing in intensity and stated that we felt this to be a poor sign prognostically. On March 24 the fetal heart sounds were not heard. However, they were heard again on the next day and continued to be heard until March 28, when the sounds were lost. On March 30 we reported again that the arteries were more dilated with but slight residual local areas of spasm and again sounded a note of alarm over the prognosis for a live baby. On April 1 M. S. went into labor and was delivered of a macerated fetus, which was thought to have been dead for several days and which weighed 1,330 Gm. The patient's blood pressure had been recorded constantly around 140/90 with but one two-day rise to 160/110.

This patient was the subject of many interesting discussions during the course of her pregnancy. While most of the observers expressed the opinion that interference was indicated, all agreed that the fetus was so small as to have rendered survival questionable. The determining factor here was the apparent lack of size of the fetus. As it turned out, interference would have given the fetus more opportunity than did "watchful waiting."

Occasionally one sees patients in whom the narrowed or spastic arteries begin to show evidence of relaxation and return to normal caliber. It is our feeling that this is a prognostic sign of fetal death or impending fetal death. In such cases, if a fetal heart sound can still be obtained, immediate interference must be considered. While one cannot make hard and fast statements about interference under these conditions, it is my opinion that if there is a probability of securing a viable child at this stage our experience would indicate that such interference must be given serious consideration.

If the termination of pregnancy does not take place during the stages of narrowing and spasm, a third stage of vascular sclerosis ensues. This marks the beginning of permanent organic changes in the vascular system. It is not always possible to state just when this transition to an organic phase ensues or how long the period of narrowing and spasm can continue before sclerosis may be assumed to be present as a permanent change. It is my opinion, based on observations of many patients before and after sympathectomy for hypertension, that ideas of what constitutes "permanent changes" in blood vessels will undergo considerable revision in the years to come.

While this statement is undoubtedly correct, it is of little aid to the clinician who has an immediate decision to make in the desire to secure a live baby without at the same time permitting permanent vascular damage to occur to the mother. He would like to have some reliable sign to guide him in forming this decision, especially if he is dealing with a small fetus and desires to ascertain how much longer he can safely wait. It is obvious that in the present state of knowledge there is available no such definite sign to give him.

In case 1 evidence of minimal arteriosclerosis was seen when the patient was admitted for her second pregnancy, although her vascular condition had never gone beyond the stage of generalized narrowing when seen during her first admission. Whether she had had preexisting minimal vascular damage prior to her first pregnancy is not known.

With continued pregnancy and narrowing and spasm the retina begins to show signs of ischemia with edema. This is first seen as grayish or fluffy areas streaming away from the disk along the course of the major vessels. This is followed by hemorrhages and transudates, forming the complete picture of the toxemic retinopathy of pregnancy. A complete or incomplete star-shaped figure may be seen in the macula during this stage. It is possible that in an already hypertensive patient such a picture may occur without the preliminary stages having been seen. All writers on the subject agree that this picture signifies permanent vascular damage and, of course, indicates a need for immediate termination of the pregnancy. The object of all treatment is to prevent the patient from reaching this advanced stage of retinopathy. Some patients, if pregnancy is terminated early in this stage, may still be delivered of live babies. In this connection the following case is interesting.

Case 3.—L. D., aged 29, was admitted to the Lying-In Hospital on May 31, 1946 with a severe preeclampsia beginning in her thirty-third week of pregnancy. Her blood pressure during her first two to three months of pregnancy was 120/80 with neither albuminuria nor other significant physical or urinary findings. Two weeks prior to admission she had had a slight amount of bright red vaginal bleeding. She had had frontal headaches and spots before her eyes for two to three days prior to admission. On admission her blood pressure was 185/120. I examined her on June 4. At that time her pupils were undilated. I reported edema of the retinas, dilatation of the veins, with full arteries and arteriovenous compressions. However, since the examination was unsatisfactory, dilation of the pupils was ordered, and the patient was reexamined on the following day. The examination disclosed blurring of the nasal disk margins, edema of the retinas, areas of spasm in some of the arteries but with no narrowing otherwise, some small deep hemorrhages and soft woolly transudates in the right macular area.

This patient had large myomas of the uterus that made it impossible to hear the fetal heart sounds. As a result of the serious ocular findings it was decided to perform a cesarean section immediately. This was done and a live 1,750 Gm. baby delivered.

I agree with Gibson [2] that there is a lack of parallelism between the degree of toxemia and the occurrence of a retinopathy.

---

[2] Gibson, G. G.: The Clinical Significance of the Retinal Changes in the Hypertensive Toxemias of Pregnancy, Am. J. Ophth. 21: 22, 1938.

Wagger, Schiotz,[3] Hallum[4] and Masters[5] have all indicated that if a retinopathy (stage of soft transudates, hemorrhages and edema) occurs prior to the twenty-eighth week of pregnancy there is only a 25 per cent chance of a live baby being born, even if the pregnancy is continued to the stage of viability, and an almost 100 per cent chance of permanent circulatory damage to the mother.

In rare cases a detachment of the retina, either unilateral or bilateral, may occur as a result of the significant intraocular edema which may be present. Here again most authors are in agreement that such an incident is an indication for immediate termination of the pregnancy. After termination spontaneous reattachment of the retinas nearly always occurs.

I find it impossible to agree with Cheney's[6] conclusion that the arterial narrowing is due to the hypertension per se and not to the presence of an acute toxemia or nephritis. We have seen too many patients with hypertension in whom such narrowing was not observed and whose pregnancies were not complicated by the eyeground findings observed in the toxemias and who have thus gone through to term uneventfully. Where prior hypertension has been present and has resulted in changes in the ocular fundi one can usually note such evidences (widening of the arterial light reflexes, compression of the veins or deflection of the veins at the arteriovenous crossings and others) unless a severe narrowing of all the vessels has taken place as a result of the toxemia, making it difficult to study individual vessel detail. I am in agreement with Hallum when he states that during the stage of narrowing the arterial light reflex loses its brightness. During this stage it is difficult to estimate the prior width of the arterial light reflex.

Mussey[7] feels that there is a definite increase in the amount and severity of the eyeground changes which is proportional to the height and duration of the hypertension. In my experience this change has not always been directly proportional to the height of the blood pressure. I have found severe spasm with a systolic blood pressure in the region of 140 to 160 and the diastolic in the neighborhood of 90. Alteration in the diastolic pressure is seemingly more important than in the more labile systolic. In at least one case I have observed an increase in a spasm that occurred in but one site in but one vessel while the blood pressure was dropping. In this case the drop in pressure was followed by a sudden severe rise; a cesarean section was immediately performed and a live baby secured. On the other hand, I have observed many patients with severer hypertension who exhibited practically no notable changes in the eyegrounds, and those patients have safely gone through their pregnancies.

OTHER OCULAR COMPLICATIONS OF PREGNANCY

Although the object of this paper is the discussion of the ocular findings in the toxemias, it might be well to mention briefly the other ocular complications occasionally found during pregnancy.

Many such complications have been reported, especially embolic or thrombotic occlusions of the branches of the central artery of the retina, vitreous hemorrhages, acute inflammations of the choroid and retina, inflammations of the cornea, uveitis, extraocular and intraocular muscle palsies, intraocular and retrobulbar neuritis, retinal detachments and amaurosis.[8] Night blindness, which has responded to therapy, has been reported in malnourished pregnant women. I have recently seen occlusion of the cilioretinal artery to the macula in one pregnant woman and a chickenpox vesicle on the cornea in another. When optic neuritis is seen, it is usually terminal. One of Schiotz' two patients with retrobulbar neuritis died, as did two of the three patients seen by Tillman.[9] Stander[10] felt that hemorrhage in the retina occurring during pernicious vomiting of pregnancy was an absolute indication for termination. I have seen one case, as has Stander, of a retinal hemorrhage occurring in a woman with severe vomiting without any other evidence of toxicity. Her vomiting ceased, the hemorrhage disappeared, and her pregnancy continued uneventfully. Such a case must be differentiated from one of pernicious vomiting.

COMMENT

All the carefully done eyeground studies in the toxemias of pregnancy indicate that such competent studies, repeated as often as necessary, serve as a great aid in the management of these cases. Occasionally the decision as to interference must be made after but one or two observations. Usually a longer period of observation is necessary and possible. Since the obstetrician usually sees his patients early in their pregnancy or even prior to conception, a study of the ocular fundi at the first visit will often give him information that may later aid him in determining whether the hypertensive changes are complicating the pregnancy or being complicated by it. It is not the province of this paper to teach ophthalmoscopy; but it is important to point out that when possible the examinations should be done after the pupils have been dilated. This can easily be done with either 2.5 per cent neo-synephrine hydrochloride or 3 per cent paredrine hydrobromide ophthalmic solution without inconveniencing the patient. It is important to carefully follow out all the four major branches of the vessels. Fresh batteries and bulbs should be used, since important pathological conditions can easily be overlooked with a poor light.

Since various patients react differently during their toxemias, with a few carrying live babies through in spite of fairly severe eye changes while others lose their babies during the stage of narrowing, it would seem advisable to consider interruption of the pregnancy as soon as pertinent eyeground changes are seen and verified by a competent observer if the fetus is viable. Watchful waiting in these cases too often may mean watching and waiting while the fetus dies, and the mother may be simultaneously acquiring permanent vascular damage. Obvi-

ously, each case must be considered individually, and no hard and fast rules can be made. However, it is my feeling that in those cases in which the fetus is viable and the eyeground signs clearly show evidence of toxemia little is to be gained by waiting, and the price of too prolonged waiting may be unusually high. Fetal death, when it does occur, is so sudden as to render twelfth hour interference impossible. When it would seem that another week or two is necessary to secure a fair chance of fetal viability, the decision obviously is dependent on all the various factors concerned in the individual case.

HYPOGLYCEMIC REACTIONS TO INSULIN

Samuel Benjamin, M.D., Washington, D. C.

Hypoglycemia may be brought about by several conditions, among which are various glandular conditions. There is hyperinsulinism as a result of islet cell tumor of the pancreas, the hypoglycemia due to Simmonds' disease of the pituitary, and hypoglycemia due to myxedematous condition of the thyroid. In addition, we have the hypoglycemia due to liver dysfunction, and the functional hypoglycemia which is considered to be on an emotional basis.

However we shall not consider these hypoglycemias here. We shall concern ourselves only with the so-called hypoglycemic reactions produced by the giving of exogenous insulin in the treatment of diabetes mellitus.

In all the previous mentioned hypoglycemias we start with a normal or below-normal fasting blood sugar. The glucose tolerance curve is either flat or below normal with one exception—the glucose tolerance curve of liver dysfunction. In that condition the curve bears a resemblance to a diabetic curve in certain features, but the fasting blood sugar is usually normal.

If we start with a normal or slightly elevated blood sugar we can see that a sudden drop need not be very severe to result in a low blood sugar level. The assumption is that the reaction itself is due to the lowness of the blood sugar level.

Now if one considers the blood sugar levels in a diabetic under insulin treatment, the conditions are not quite the same. The postprandial blood sugar levels are usually high and frequently there is nocturnal elevation, although under these conditions the fasting blood sugars may be normal. Under these conditions diabetics can and do have sudden marked drops in blood sugar levels without necessarily reaching hypoglycemic levels. In the presence of these circumstances there are insulin reactions.

It is interesting to note that in an article published by Wauchope, entitled "Hypoglycemia, a Critical Review,"[1] he reports a case from Payne and Poulton of a diabetic 46 years of age in whom a fall from a 0.320 to a 0.280 mg. blood sugar level regularly produced symptoms. He also reports a case from Harrison in which the patient exhibited no symptoms despite a fall of blood sugar level from 0.328 to 0.053 mg. in five hours. Harrison made 28 estimations of blood sugar levels on 11 children under 12 years of age. Despite the fact that the levels were less than 0.050 mg., the lowest being 0.028 mg., there were no symptoms of insulin reactions.

Rice has observed one diabetic with a blood sugar too low to be read, walking around. I have observed a similar patient. Both patients were juvenile diabetics.

From various observations and reports, it seems that insulin reactions are based not on low blood sugar levels but rather on rapidity of drop, although in a good many cases there may be both.

It is vital that these facts be universally known in order to facilitate prompt and accurate recognition of insulin reactions. One must not be misled by the higher blood sugar levels. I believe, in view of the above facts, that we would be more nearly correct in discarding the terminology of hypoglycemic reaction as applied to the diabetic and substituting the terminology of insulin reaction, insulin shock, and insulin coma.

If we delete the term hypoglycemia, we are not so likely to be misled in cases in insulin reaction when the blood sugar is not at a hypoglycemic level. It is true that the chances of high blood sugar in insulin coma are small. However in overlooking an insulin reaction with a relatively high blood sugar, one may put the patient into insulin coma by the giving of insulin instead of glucose.

Let us consider the urinary findings in insulin reaction as an aid in diagnosis. We have been accustomed to believe that the urine should be negative for sugar and acetone in insulin reactions. When this is so, these findings aid in the diagnosis. However, we should not rely on them alone, for it is possible to have insulin reaction not only in the presence of glycosuria but also in the presence of acetone. This is true particularly in the transitional state when a patient is being treated for diabetic acidosis or coma.

We shall now consider the diagnosis, symptoms and treatment of insulin reactions. Most important is the early recognition of the reaction. Sudden onset is usually characteristic. Symptoms vary greatly. The so-called classic symptoms are sweating, hunger, internal tremor (subjective), external tremor, weakness, and nervousness. Some of the nonclassic symptoms are diplopia, blurred vision, headache, parasthesias, motor aphasia, muscular twitchings, anginoid attacks, nausea and vomiting (protamine zinc insulin), and bizarre psychic phenomena.

Symptoms not only vary greatly in different patients but also vary greatly in the same patient. The following cases are illustrative.

Case 1.—Mrs. E. McD., aged 28 years, has been a known diabetic for two years. At various times, her insulin reactions have caused hysteria and screaming—a feeling that she was los-

---

Delivered at the Third Annual Clinical Session of the American Medical Association, Washington, D. C., Dec. 7, 1949.

[1] Wauchope, G. M.: Hypoglycemia, a Critical Review, Quart. J. Med. 27: 117 (Jan.) 1933.

ing her mind (this was while she was taking regular insulin). Since she has been taking protamine zinc insulin, her reactions have simulated intoxication with staggering. The patient spilt a quart of milk on the floor and spent an entire afternoon mopping it up with a potholder. At another time she had no symptoms of reaction except to attempt opening a door by using a match in the keyhole. On occasion she has no warning but becomes unconscious. Her reactions at present occur during sleep. There are no sweaty reactions during the day, but they do occur at night. She has no memory of these symptoms at any time after the reactions.

Case 2.—Mrs. D. S., aged 25, has had diabetes for 20 years. This patient's description of her varied reactions is most graphic.

"On several different occasions I have been sitting in the office typing, and, for no reason at all, my teeth would start to chatter, and would soon sound like rapid machine-gun fire. After drinking some orange juice, they would stop. However, when this happened the first time I had to call the doctor before I would take any orange juice. Now, I know better.

"While watching the feature of a movie, I would suddenly find myself seeing twice as many characters on the screen as there should be, and on closing one eye, I would see the correct number. At times like this I generally sit with one eye closed for several minutes, until it becomes tiresome, and I then realize that I should eat some sugar, and do so. Seeing double would be the only symptom I would have on such occasions.

"Under ordinary circumstances I know that I am a very stubborn person, but under the influence of insulin I know that I can be twice as stubborn. At such times I will refuse to drink orange juice, and when someone brings it to me, I just look at it, clench my teeth and shake my head. However, after a lot of coaxing and a certain amount of firmness, I will finally drink it down and then probably ask for more. I don't know whether I distrust the person who is trying to help me, or whether I don't believe it is orange juice, or what—but I do know that I stubbornly refuse to drink it. . . .

"A frozen, tingling sensation around my nose, mouth and tongue happens to me quite frequently. It is a feeling such as you get when the dentist gives you novocaine before working on a tooth. I have also had my whole hand stay numb for days on end, and yet I would not think I had a reaction. This sort of sensation always lasts for quite a while after I get over the reaction.

"One of my most recent reactions was, I think, the most peculiar. It happened one Saturday afternoon just a short time after I had finished lunch. I was sitting in the living room reading, and suddenly started to feel light-headed. I stopped reading and continued to sit where I was, but I seemed to get more light-headed by the second. Not knowing what was wrong, and again not thinking of an insulin reaction, I stood up, thinking I would go to my room and lie down, but I couldn't take more than a couple of steps, for I just seemed to fall apart. And I fell completely apart! My legs I was sure were about two feet out in front of me, my head was dancing somewhere above me, and when I reached out to grab the wall, my arms being off, they were of no use whatsoever either, so I yelled for help, and my roommate caught me just as I was slipping down the wall. Somehow or other, she managed to get me to my room and onto the bed. She then called the doctor and told him that I said I was falling apart. By this time I was crying desperately and repeating over and over again that I was falling apart. The doctor ordered orange juice, and after two glasses of it, I gradually collected my scattered wits and limbs, and upon checking, found that my arms, legs and head were all attached and exactly where they should be. The best way I can think of to illustrate this feeling is by mentioning a skeleton, of which I am sure almost everyone has seen cartoons, where it dances in a very grotesque fashion—usually to the tune of 'The Dance Macabre'—wherein it rattles around and all the bones fall apart, and then it becomes completely disjointed and then comes together again. That is exactly how I felt, for with my head bouncing around in the air, I just couldn't control my arms and legs."

The blood sugar level may be low, normal or high. The urine may be negative for sugar or may have glucose or even acetone. If we remember all these facts and that symptoms are very variable, that the classic symptoms may be absent, and that sweating which is considered one of the most constant symptoms, may be entirely absent, many insulin reactions will not be overlooked. In addition, we must never forget that insulin reactions enter into the psychic realm and may be manifested by a psychic disturbance ranging from hysteria to mania.

If we follow the rule, "In known diabetics under treatment with insulin, any psychological deviation may be an insulin reaction," and institute treatment, we will avoid many accidents and tragedies.

The clinical knowledge of insulin reactions in general and the specific knowledge of a patient's reactions to insulin are the best criteria for the diagnosis of insulin reactions. If the laboratory findings fit in, accept them; otherwise reject them.

It should be remembered that giving glucose will do no great harm in an impending acidosis, but that giving insulin to a patient in insulin reaction may mean permanent brain damage and/or death.

In the treatment of insulin reactions, the promptness of treatment determines the degree of recovery. Sugar or fruit juice should be administered as soon as the reaction is recognized. Do not delay; coma may develop rapidly. During the precoma state, the patient may become refractory to taking anything by mouth after a wait of only a few minutes. This is part of the insulin reaction. When the patient is taking a slow-acting insulin, bread and milk should be given after the fruit juice. The carbohydrates of the latter are not so quickly absorbed. Intravenous administration of dextrose may be necessary in addition to oral ingestion of sugars, as patients often do not respond as quickly to orally ingested sugars alone. The effects of prolonged hypoglycemia on the brain are not always relieved by bringing the blood sugar level back to normal or above. In my own experience I recall a patient who lost his ability to articulate during an insulin reaction. In spite of the fact that his blood sugar level was permitted to rise to 0.387 mg., this sign lasted for five days.

SUMMARY

Hypoglycemia is a misleading term for the abnormal reaction of a diabetic to insulin. It is recommended that this term be replaced by insulin reaction, insulin shock, and insulin coma. The principal criterion for diagnosis of these conditions should be clinical observation based on a good knowledge of insulin reactions in general and a specific knowledge of the reactions of the individual patient, plus the laboratory findings only if they fit into the picture.

Glucose given in impending acidosis or coma can do little harm compared to the inestimable damage that may result from giving insulin in insulin reactions. When in doubt, always give glucose.

Farragut Medical Building.

The Medical Triangle.—The three sides of the medical triangle are made up of the doctor, the patient and the disease. Success in the medical profession is largely dependent upon the relation of these three sides. One of the dangers of modern institutional medicine is the over-emphasis of the positive facts concerning the disease, to the exclusion of the human sufferer and the suppression of the interaction between the personalities of the doctor and the patient. In some kinds of private practice the reverse may be the case.—*British Journal of Physical Medicine*, January, 1951, page 15.

CLINICAL NOTES

ALKAPTONURIA

Carl L. Mauser, M.D., Oakland, Calif.

Alkaptonuria is a rare disease of very little clinical importance except that it may be confused with other conditions, particularly glycosuria of diabetes mellitus. The etiological factor is apparently due to an inborn error in protein metabolism resulting in the excretion of homogentisic acid in the urine. The two amino acids which have been incriminated as the source of abnormal metabolism are tyrosine and phenylalanine. These two amino acids are the source of homogentisic acid. The clinical manifestations of alkaptonuria were first described by Marcet[1] in 1823. However, the nature of the reducing material in the urine was first recognized by Marshall.[2] The condition is thought to be hereditary; however, this is not always proved. The patient with alkaptonuria usually has no clinical manifestations unless he has pigmentation of the cartilages, then called ochronosis. The condition is felt to be completely benign. The urine on standing becomes alkaline and gradually turns brown to black with oxidation of the homogentisic acids. Homogentisic acid itself reduces alkaline solutions such as Benedict's or Fehling's and may thus be mistaken for glycosuria. It does not, however, reduce an alkaline bismuth solution, such as Nylander's reagent. Homogentisic acid forms a black precipitate when 10% sodium hydroxide solution is added to urine containing it. Other tests which may be of benefit are that homogentisic acid does not ferment yeast, and it does not rotate polarized glucose, but with the addition of dilute ferric chloride solution a transitory deep blue color is formed until oxidation is complete.

Another simple test for the presence of homogentisic acid depends upon the relationship of hydroquinone. A drop of urine which has been made alkaline is placed on sensitized photographic paper; the paper immediately becomes black. This color change does not occur with normal urine constituents.

SYMPTOMATOLOGY

There is a triad of symptoms which sometimes are recognized: (1) pigmentation of the scleras and ears; (2) dark color of the urine; (3) arthritis.

The pigmentation lies in the fibrocartilagenous structures, the scleras, the center external cartilages, the tendons, and the skin. In a good many cases, the scleras take on a diffuse gray color and frequently a semilunar or V-shaped patch of pigmentation occurs in both scleras. Sometimes this pigmentation acquires the size of a bean and is situated midway between the margin of the cornea on the outer or inner canthus. This color may vary from deep brown to black.

The pigmentation of the cartilages and fibrous tissues is visible only in certain locations, the most characteristic of which is the ear. The skin of the face may be involved and often is described as a coffee-colored pigmentation. In other cases there is a uniform yellow-brown color with intensification over the cheeks. In some cases the color of the skin has been described as "pure melanosis, just as if a patch of the blackest Negro skin had been inserted."

Arthritis, usually of a hypertrophic type, is very frequent in alkaptonuria. The bony changes may be indistinguishable from those of osteomalacia, except for the absence of pigments in the latter disease. Alkaptonuria, or ochronosis, usually runs a chronic course over many years and terminates usually with some affection of the arterial system. However, prognosis is good for life expectancy. Treatment is usually one of prophylaxis, such as the avoiding of prolonged use of phenol preparations. Being either a congenital or a familial disease, alkaptonuria can be prevented only by forbidding intermarriage in affected families.

REPORT OF A CASE

The patient was a white boy aged 8 years, first seen Feb. 14, 1950, after a physician in a neighboring city had found that the child had sugar in his urine. It is of some interest to know that three years prior the youngster was treated for diabetes mellitus for a period of several months. Why treatment was discontinued is not known. Reactions of the urine to Benedict's solution apparently were all black, but no blood sugar determinations were made at that time. On the day prior to my seeing the youngster for the first time, he was taken to a physician because of a cold and a urinalysis revealed a reaction to Benedict's solution. He had no symptoms referable to diabetes. There was no polyuria, polydypsia, or polyphagia. He had lost no weight and had no thirst; there was no blurring of vision; his skin texture was normal, and he healed normally. There was no known history of diabetes on either the maternal or the paternal side of the family. The child gave a history of frequent head and chest colds throughout the year which were usually quite prolonged. A review by systems otherwise was essentially noncontributory.

Physical examination.—The patient was a rather dusky-complexioned, white boy of 8 years who was well nourished. He weighed 69 lb. (31.3 kg.). The pupils of the eyes were regular and equal and reacted to light. The scleras and conjunctivas were slightly injected. The disks of the fundi were sharp; the vessels were normal; there were no infiltrations or hemorrhages elicited. The mucous membranes of the nose were pale and boggy; ventilation was limited bilaterally, and there was a good deal of discharge posteriorly. The teeth were in good repair and were normal for the child's age. There were no caries. The posterior pharynx was clear, and the tonsils had been extirpated. The tympanitic membranes were normal but slightly retracted. There was no adenopathy in the neck. The chest was symmetrical, resonant and well clothed. The lungs were clear to percussion and auscultation. The left border of the heart was in the midclavicular line in the fifth left interspace. The pulse rate was 88. There were no murmurs or thrills elicited. His reflexes were physiological. The abdomen was soft and scaphoid. There were no palpable abnormal masses or viscera, and tenderness was not elicited. The genitals were normal; the testicles were both in the scrotum. The axillas were normal.

Laboratory studies revealed the following values:

2/14/50.—Blood sugar (micro method), 117 mg./100 cc.
2/15/50.—Glucose tolerance (micro method):
    Fasting 98 mg./100 cc.; urine, dark green
    30 min. 170 mg./100 cc.; urine, dark green
    60 min. 158 mg./100 cc.; urine, dark green
    2 hr. 128 mg./100 cc.; urine, dark green
    3 hr. 116 mg./100 cc.; urine, dark green
2/17/50.—Blood sugar (micro method), 103 mg./100 cc.
3/ 4/50.—Blood sugar (micro method), 127 mg./100 cc.
    Urine turned black on standing.

He was tested for homogentisic acid in his urine, with both the 10 per cent ferric chloride test and the 10 per cent sodium hydroxide test eliciting positive reactions.

---

[1] Marcet, A.: Tr. Med.-Chir. Soc. Edinburgh **12**: 37-45, 1822-1823.

[2] Marshall, J.: M. News **50**: 35, 1887.

The youngster was given skin tests with all the important foods and inhalants and gave reactions to many inhalants which were indigenous to his environment, which undoubtedly had a good deal to do with his frequent colds.

This case has been reported because of its academic interest and its severity. This child did not manifest the articular reactions frequently seen in this condition but did manifest the urinary and pigment changes in the skin. He had been treated for diabetes mellitus and it can be seen that it is possible to confuse these two conditions. When diabetes mellitus is suspected, certainly a blood sugar determination should be done. As the prognosis is good for normal span of life, no treatment is indicated.

NONTHROMBOCYTOPENIC PURPURA CAUSED BY MENTHOLATED CIGARETTES

Benjamin Highstein, M.D.
and
Israel Zeligman, M.D., D. Med. Sci., Baltimore

Menthol is a very useful and nontoxic drug prescribed mainly for its analgesic properties. It is used frequently for dermatoses because of its anesthetic and cooling effect and in the form of nose drops or sprays, cough drops, and medicated cigarettes for rhinitis, pharyngitis, laryngitis, and bronchitis. Like other essential oils, it is also used occasionally as a carminative.

Menthol causes relatively few allergic reactions. It is a well-recognized cause of the eczematous contact type of dermatitis, but in a study of the literature we were unable to find any other allergic reactions recorded.

The present report is that of a case of nonthrombocytopenic purpura caused by menthol present in medicated cigarettes. " 'Kool' cigarettes [1] are cigarettes containing U.S.P. grade menthol added to a blend of domestic Bright and Burley tobaccos and imported Turkish tobaccos." They are used by smokers because of the cooling effect of menthol on the mucous membranes of the mouth and pharynx.

REPORT OF A CASE

A. S., a white housewife and charwoman, aged 36, was first seen June 6, 1949, because of a generalized rash. The family history was essentially noncontributory except that her mother, aged 65 years, had Ménières disease. She, herself, had always been well, except for chronic frontal sinusitis of 15 years' duration. She had never previously had dermatoses or allergic manifestations.

The eruption had begun rather insidiously in November, 1948, with only a few scattered lesions on her arms and legs. By March, 1949, the asymptomatic rash had spread rapidly and profusely. She was a well-nourished, rather plethoric white woman in no obvious discomfort. Except for the eruption, the physical examination was completely noncontributory.

The eruption was symmetrically distributed over the hands, forearms, arms axillary folds, thighs, and legs. Hundreds of purpuric macules varying in size from 1 to 5 mm. were present. Telangiectatic macular lesions were also present on the palms, palmar surfaces of the fingers, the nose, cheeks, and upper chest. No mucous membrane lesions were noted. The clinical impression was purpura. Biopsy of a lesion on the forearm was consistent with purpura; there was hemorrhage into the cutis with edema and some diffuse as well as perivascular cellular infiltration consisting mainly of lymphocytes with a few mononuclear cells.

The erythrocyte count was 5 million per cubic millimeter with a hemoglobin value of 14.5 gm. per 100 cc. (equal to 100%). The leucocyte count was 14,000 per cubic millimeter, with a differential count of mature polymorphonuclear leucocytes, 68%; small lymphocytes, 20%; large lymphocytes, 9%; and eosinophiles, 3%. Platelets numbered 180,000 per cubic millimeter and the bleeding time 5 min. 15 sec. The coagulation time was increased to 12 min. and the erythrocyte fragility test was abnormal with hemolysis at 0.46 to 0.4% saline solution (normal 0.44 to 0.34% saline solution).

Our clinical impression was that of a nonthrombocytopenic purpura. Every effort was made to investigate a possible drug etiology. She denied all recent medication, but admitted to rather large doses of acetylsalicylic acid years ago for sinusitis. Late in February, 1949, long after the eruption had appeared, she had taken a proprietary medication containing quinine, acetylsalicylic acid, ephedrine sulfate, magnesium hydroxide, caffeine citrate, and sodium salicylate for only two days.

The patient was treated with vitamin K, rutin, and ascorbic acid without improvement for two weeks. On July 1, 1949, she mentioned that she had been smoking one to two packs of kool® cigarettes since September, 1948, two months prior to the appearance of her eruption. Kool® cigarettes were then interdicted, and at the same time she resumed the smoking of nonmedicated cigarettes. The eruption had improved approximately 75% when seen Aug. 2, 1949 and had completely disappeared when examined Aug. 22, 1949. A hemogram at this time was normal with normal blood coagulation time and erythrocyte fragility test.

On Sept. 1, 1949, with her skin normal, she was begun on a test dose of menthol, 1 grain (60 mg.) three times daily, for a period of 14 days. Upon examination Sept. 15, 1949, the purpuric eruption had recurred on the upper and lower extremities, about a third as profusely as when originally seen. At this time the coagulation time had again increased to 9 min. with the remainder of the hemogram normal. The drug was discontinued, and by Oct. 15, 1949, the purpura had disappeared and the blood coagulation time had returned to normal.

The patient thereupon was instructed to resume smoking the mentholated cigarettes, and by Dec. 23, 1949, some purpuric lesions had reappeared on the upper and lower extremities and on the face. Discontinuing the medicated cigarettes and substituting nonmentholated cigarettes again resulted in complete disappearance of the eruption when seen Jan. 18, 1950. Since then she has had a mild recurrence on her face and extremities when she smoked a pack of kool® cigarettes daily for several weeks.

When last seen, Oct. 1, 1950, the patient had not smoked kool® cigarettes for the past three months and showed no evidence of purpura.

SUMMARY

A case of nonthrombocytopenic purpura caused by mentholated cigarettes is reported. The rash first appeared about two months after our patient began smoking one to two packs of mentholated cigarettes daily. The eruption disappeared when she discontinued smoking the medicated cigarettes, and it was experimentally reproduced when she ingested 1 grain (60 mg.) of menthol three times daily, and also on several occasions when she resumed smoking the mentholated cigarettes. The only consistent hematologic abnormality which paralleled the purpuric eruption was an increase in the blood coagulation time.

Our review of the literature revealed no other such case reported.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

The Council wishes to express its appreciation for the valuable cooperation of the Advisory Committee on Audiometers and Hearing Aids for its expert services. The Committee members are Drs. Gordon Berry, Richard K. Cook, Hallowell Davis, Kenneth M. Day, Edmund P. Fowler, Isaac H. Jones, Dean M. Lierle, M. H. Lurie, Douglas Macfarlan and C. Stewart Nash.

Howard A. Carter, *Secretary.*

AUDIOMETRY AT HIGHER FREQUENCIES

The Advisory Committee on Audiometers and Hearing Aids wishes to call the attention of all those engaged in audiometry to certain facts concerning sounds above 6,000 cycles per second. The facts seem to be generally unknown or overlooked and may cause unfortunate errors of screening, prognosis and diagnosis. The facts are:

(*a*) There is no accepted normal threshold of hearing for any frequency above 8,000 cycles per second (cps.).[1]

(*b*) The currently accepted normal threshold of hearing for 8,000 cps. is under criticism and will undoubtedly be revised if sufficient reliable data to support the current criticisms are accumulated.

(*c*) In view of the uncertainty about the correct normal value for 8,000 cps. any extrapolation of the normal threshold curve to higher frequencies can be considered as only a very rough approximation.

(*d*) The scatter (standard deviation) of thresholds at 8,000 cps. and at 4,000 cps. is considerably greater than at lower frequencies.

(*e*) Physical measurements of the pressure output of an audiometer earphone begin to be difficult and uncertain at 6,000 cps. and are very unreliable at 12,000 cps. (American Standard Method for the Coupler Calibration of Earphones, Z24.9-1949.) This is due to purely physical [2] relationships between the wavelengths of the high frequency sounds and the necessary dimensions of the "coupler" in which the acoustic pressure is measured.

(*f*) At frequencies above about 8,000 cps. current audiometer earphones are relatively inefficient and are also subject to large variations from one receiver to another, even among those of the same model.

(*g*) Resonances within the ear canal are very important at high frequencies and these resonances vary with the size and shape of the canal and also with minor changes in the placement of receivers over the ears.[3] For example, in a recent test in a referee laboratory a systematic difference of several decibels was introduced by a slight variation in the thickness of the rubber cushion over the face of the receiver.

For these various reasons the Advisory Committee on Audiometers and Hearing Aids has added a new stipulation to its minimum requirements for pure tone audiometers for diagnostic purposes, and also for screening audiometers, regarding any test frequencies above 8,000 cps. as follows: If any such frequencies are provided as test frequencies it must be clearly indicated on the audiometer that any measurements made at such frequencies are only rough approximations. In the opinion of the Committee such high frequencies in an audiometer are only of qualitative value and it is misleading to record in decibels any hearing losses above 8,000 cps. This situation is not likely to be improved by advances in the art or science of acoustics since it depends in large part on biological variability in the anatomy of the ear canal as well as on certain inescapable physical relationships that involve the wavelength of sound. The Advisory Committee further recommends caution in the interpretation of hearing losses determined at 8,000 cps.

Implicit in these propositions is a fundamental criticism of any screening test that employs frequencies above 6,000 cps. The Advisory Committee on Audiometers and Hearing Aids will not recommend acceptance by the Council on Physical Medicine and Rehabilitation of any apparatus designed to employ frequencies above 6,000 cps. The Advisory Committee therefore suggests that users of audiometric tests reexamine their technics and instruments with care and determine whether or not these can be restandardized using the frequency 6,000 cps. in place of the higher ones.

The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

Howard A. Carter, *Secretary.*

SILICONE BOUNCING PUTTY ACCEPTED

Manufacturer: General Electric Company, Waterford, N. Y.

Distributor: S. R. Gittens, 1620 Callowhill Street, Philadelphia 30.

Silicone Bouncing Putty is recommended by the manufacturer for therapeutic exercise of the fingers. It is marketed in cans each containing 2 ounces (57 Gm.) of the substance. It is a member of the silicone family, a class of organic compounds in which certain carbon atoms are replaced by silicon atoms. It is generally assumed that in the oily, greasy, rubbery and putty-like members of this class there are molecular chains consisting of alternate silicon and oxygen atoms thus: -O-Si-O-Si-O-. The silicon atoms, being quadrivalent like carbon, furnish attachments for side-chains containing carbon and other elements.

Its physical properties are unusually independent of temperature and unusually dependent on time. Given time, the Bouncing Putty flows like a liquid, and its viscosity at the boiling point of water is little different from its viscosity at subzero temperatures. But if struck suddenly, or if dropped on the floor, it bounces with an extraordinary resilience. It is not decomposed by the process of autoclaving ordinarily used in sterilizing surgical materials.

The substance is marketed simply with the claim that it is useful in some kinds of therapeutic exercise for the hands. The Council on Physical Medicine and Rehabilitation obtained evidence that this claim was justified, and voted to include Silicone Bouncing Putty in its list of accepted devices.

THERA-PLAST ACCEPTED

Manufacturer: Thera-Plast Co., 154 Nassau Street, New York 38.

Thera-Plast is a silicone (compound of carbon, oxygen and silicon) proposed for use in therapeutic exercises for the hands. While some compounds of the silicone group are oily or rubbery, Thera-Plast is a semi-solid which at first sight resembles putty. It differs from putty in two respects, however. On the one hand it is distinctly liquid, and slowly spreads out on a flat surface or takes the shape of its container; on the other, it is extremely resilient to sudden shocks and, if it is not shattered, will bounce like rubber. It is practically unaffected, either physically or chemically, by water at freezing and boiling temperatures. It is supplied in tins containing 57 Gm. (2 ounces) of the silicone.

As a material for therapeutic exercise it differs from putty in that it will yield even to the weakest pressure if given time. It also differs from rubber objects of various forms in that it does not retain any given shape for more than a few seconds.

From sources acceptable to the Council evidence was obtained that this substance was useful in some types of therapeutic exercise. The Council on Physical Medicine and Rehabilitation voted to include Thera-Plast in its list of accepted devices.

THE ATLANTIC CITY MEETING

Elsewhere in THE JOURNAL are an abstract of the Proceedings of the House of Delegates and a review of some of the other activities at the recent annual session of the American Medical Association. This meeting, which was held in Atlantic City, was attended by approximately 12,000 physicians, who, with their families, helped swell the total registered attendance to more than 32,000. The scientific programs and descriptions of the technical exhibits were listed in an earlier issue of THE JOURNAL (April 14, 1951). Many of the papers that were presented at the Section meetings will appear in coming issues of THE JOURNAL, but some months necessarily will elapse before all the communications that are accepted for publication in THE JOURNAL can appear in print. Some of the papers that do not appear in THE JOURNAL will be published in the specialty journals.

It is impossible to present in a summary all that occurred at the meeting. It also is impossible to direct attention to the many fine contributions made by those who presented papers or exhibits. Lack of space alone is a sufficient limiting factor. However, for physicians who did not attend this 100th annual meeting of the American Medical Association, a brief survey of some of the occurrences that were somewhat extensively commented on by those in attendance has been prepared and appears in the Organization Section of this issue. In the past it has been customary to offer an editorial immediately after the meeting, but in an attempt to provide more extensive coverage this newer approach is offered. It may fail to reach its objective, but the Editor would be interested in the reactions of the readers so that plans for future meetings may be made.

A QUOTA BASIS FOR THE APPOINTMENT OF INTERNS

In this issue of THE JOURNAL, the Council on Medical Education and Hospitals announces the establishment of quotas for the appointment of interns to become effective July 1, 1952. The announcement points out that, as a result of an increasing demand by hospitals for the services of interns over the past 10 years, the number of internships offered by approved hospitals now exceeds the number of available applicants by at least 3,000. This disparity has given rise to many undesirable consequences, some of which seriously threaten the integrity of the whole program of intern training. The exertion of undue influence on prospective applicants, overstaffing with interns in some hospitals and emphasis on noneducational aspects of the internship in other hospitals, are cited as some of the undesirable results of the present situation which make necessary the establishment of internship quotas, even though limitations of this type are distasteful.

To correct these conditions which have arisen in the present unwholesome competition for interns, the Council has established a quota system to be computed on the basis of a percentage of the number of internships offered in 1950 or the total number offered in 1940, whichever is the greater. This dual basis has been adopted so as to avoid penalizing those hospitals that have not increased their requirements for interns during the period concerned. The reduction in the number of internships to be offered in hospitals requesting the Council's approval will bring the number of positions into approximate balance with the number of applicants available to fill them. There will, however, still be a sufficient excess of internships offered to permit freedom of choice by the applicant and to stimulate hospitals to reasonable competition for applicants from the standpoint of their educational programs.

The first list of hospitals approved on this basis will appear in the 1951 Internship and Residency Number, scheduled for publication Sept. 29, 1951. It is anticipated that hospitals approved by the Council will recognize the necessity for the establishment of this quota system and that a readjustment of hospital service can be made without impairment of the quality of patient care.

PRODUCTION OF PHYSICIANS: POLICY OF THE AMERICAN MEDICAL ASSOCIATION

There has been sufficiently widespread misunderstanding of the American Medical Association's attitudes and activities with respect to the production of physicians to make desirable the preparation of a statement summarizing the Association's policy on this subject. At the recent meeting in Atlantic City, the Council on Medical Education and Hospitals in a special report to the House of Delegates set forth a clear positive statement summarizing the Association's position on this important subject. This report was unanimously approved by the House of Delegates as a reaffirmation of official policy.

The full text of the report is published on page 865 of this issue of THE JOURNAL. Stating that the American Medical Association has no desire to limit the production of properly trained physicians to serve the American people, the report points out that all medical schools in operation in the United States at present are fully approved by the American Medical Association and the number of schools approved is determined entirely by the ability of schools to meet acceptable educational standards. The report further emphasizes that the number of students admitted to individual schools is determined by the proper authorities in each school in accordance with the school's educational philosophy and its own judgment of its educational resources. The American Medical Association may advise a school to reduce its enrolment only when there has been an enrolment increase considerably in excess of increases in facilities.

The report summarizes the increase in the number of students in approved medical schools since the Council published its first list of approved medical schools in 1910. It points out that, within the last 10 years alone, the number of medical students has increased by almost 5,000, which is the equivalent of creating at least 15 new medical schools of average size. Cognizance is also taken of the important activities of state medical societies in providing effective leadership in the establishment of new medical schools and the expansion of existing schools. Attention is also called to the fact that the American Medical Association has facilitated the entrance into practice in this country of physicians educated abroad, a policy which in itself should make it clear that the Association does *not* attempt for selfish reasons to limit the number of physicians practicing in the United States. The statement concludes with the pledge that the Association will in the future continue its efforts to maintain high standards of medical education and to support expanding programs of medical education in the interest of the American people.

While discussions of the present adequacy of the supply of physicians will undoubtedly continue, the publication of this statement should serve the useful purpose of helping to keep the debate focused on the subject and not permitting it to become an unjustifiable attack on the medical profession.

PLASMA L. E. TEST IN LUPUS ERYTHEMATOSUS

Disseminated lupus erythematosus is a prolonged febrile disease which may superficially resemble rheumatic fever and rheumatoid arthritis. The diagnosis may be extremely difficult in the absence of cutaneous manifestations. Hargraves, Richmond, and Morton [1] observed in bone marrow preparations two types of cells which have not been previously described. One cell, which they designated as a "tart" cell, appears to be a histiocyte or a monocytoid reticuloendothelial cell that contains a second characteristic nucleus within the Hof of the primary nucleus. This cell was found in practically all bone marrows. It was present in increased numbers in bone marrow preparations from patients with lymphoblastoma, pulmonary infection, or metastatic carcinoma. The second cell described was referred to as an "L. E." cell and was found in the bone marrow only in patients with acute disseminated lupus erythematosus. The L. E. cell is a mature neutrophilic polymorphonuclear leukocyte, which differs from the tart cell by the difference in the structure of the engulfed material. In the L. E. cell the engulfed mass, characterized by lack of chromatin structure, is almost homogeneous and has a smoky appearance. In the tart cell the chromatin structure of the engulfed material resembles the nucleus of a lymphocyte. The L. E. cell is apparently the result of a lytic-phagocytic action. This interesting phenomenon was observed only in the bone marrow in certain cases of acute disseminated lupus erythematosus. These findings were corroborated by Haserick and Sundberg,[2] who demonstrated the L. E. cell in four out of five cases of acute disseminated lupus erythematosus but were unable to find it in any other condition in which leukopenia was prominent. They believed that the observation of L. E. cells will aid in the diagnosis of disseminated lupus erythematosus in cases in which skin manifestations are lacking.

Hargraves [3] could not demonstrate L. E. cells in direct smears of bone marrow. By the addition of anticoagulants to the peripheral blood and centrifugation of the material, L. E. cells could be demonstrated in smears from the buffy coat layer. In cases in which bone marrow had been positive, L. E. cells were found in small numbers in the peripheral blood. Sundberg and Lick,[4] on concentrating the material, have likewise found L. E. cells in the peripheral blood.

Hargraves conceived the idea that the factor responsible for nucleolysis, agglutination, and phagocytosis as observed in the L. E. cell might well be in the plasma of patients with acute disseminated lupus erythematosus and that it would be possible to reproduce L. E. cells with the use of bone marrow from patients who did not have the disease. Using plasma obtained from venous blood of patients with acute disseminated lupus erythematosus, he placed into it bone marrow material obtained from patients with various other diseases. The mixture was incubated at body temperature for a short time, and concentrated preparations were made from it. Typical L. E. cells, as well as the phenomenon of nucleolysis and agglutination, were observed. Haserick [5] has made the same observation; he concluded that the plasma of patients with acute disseminated lupus erythematosus contains a factor that induces the formation of rosettes of leukocytes and characteristic inclusion-containing cells (L. E.) when mixed with normal bone marrow preparations. The particular factor was contained in the gamma globulin fraction of plasma in acute disseminated lupus erythematosus. The L. E. factor disappeared from the blood during remissions of the disease and reappeared during relapses.

Lee and his associates [6] found the L. E. cell in peripheral blood and bone marrow in all of 17 proved cases of acute disseminated lupus erythematosus. The cells were usually present in greater numbers in the marrow. They were not able to demonstrate the L. E. cell in diffuse vascular disease, rheumatoid arthritis, dermatomyositis, scleroderma, rheumatic heart disease and subacute bacterial endocarditis.

Haserick [7] reports in a recent communication on 23 patients with systemic lupus erythematosus with L. E. cells in the plasma. The test was found also to be positive in less fulminating cases, in many of which the clinical

history was not typical for acute disseminated lupus erythematosus. Among such cases there were unusual combinations of rheumatoid arthritis and epilepsy. These variations from the typical concept of acute disseminated lupus erythematosus suggested that (1) the plasma L. E. test can be positive in diseases other than acute disseminated lupus erythematosus, i. e., false positive L. E. tests can occur, or (2) acute disseminated lupus erythematosus is actually a frequent, protean disease with an atypical phase that may be detected with certainty with the plasma L. E. test. From the clinical and laboratory data found in the 23 patients, it was evident that a positive plasma L. E. test is associated with systemic lupus erythematosus although the presenting signs and symptoms may be suggestive of any of a group of diseases that Klemperer and his co-workers designated as collagen diseases. Haserick concludes that a patient with "atypical rheumatoid arthritis" or "rheumatic fever" and positive serologic reactions for syphilis may in reality have lupus erythematosus and false positive reactions for syphilis. Similarly, an epileptic person with one or more of the signs of so-called collagen disease may have a positive L. E. test to account for the convulsive seizures.

The plasma L. E. test is a valuable diagnostic test in systemic lupus erythematosus. The test may correlate many seemingly unrelated conditions under the diagnosis of systemic lupus erythematosus. The reaction continues positive longer than the reaction to any other laboratory test during remissions of lupus erythematosus.

SURGICAL TREATMENT OF FOCAL EPILEPSY

Most patients with chronic epilepsy can be more or less successfully treated with anticonvulsant drugs, psychotherapy and occupational rehabilitation. Anticonvulsant medication, according to Walker,[1] will eliminate the attacks in more than 50% of the cases and markedly decrease seizures in another 25%. It is in the resistant 25% that surgical treatment may be considered. This type of treatment is applicable to cases of focal epilepsy. Diagnosis of focal epilepsy is arrived at by a careful study of the clinical history of the patient, in particular of the character of the seizures, of electroencephalograms, roentgenograms of the skull, pneumoencephalograms and cerebral angiograms. The character of the seizures is so important for the diagnosis that at times it is advisable to bring on an attack by intravenous injection of pentylenetetrazole. The provoked seizures have all the characteristics of a spontaneous one. Electroencephalogram has become an indispensable test in the diagnosis of epilepsy. Convulsive activity is accompanied by rapid fluctuations of electrical potential, giving the encephalogram the appearance of a series of spikes. Patients with chronic epilepsy due to cortical damage have, as a rule, localized electroencephalographic alterations in the form of a slow wave focus with or without spiking.

Cerebral seizures may be caused by a variety of focal lesions, such as meningocerebral scar, local cortical atrophy, local microgyria, expanding lesions, such as brain tumor or cerebral abscess, cysts and other abnormalities. According to Penfield all of these lesions have a common feature, namely, the presence of a zone or area of ganglion cells in which the circulation has been interfered with to such an extent that the life of the cells is threatened. It is at some point in these peripheral and partially destroyed zones that the actual focus in which the epileptic discharge originates is to be found. Partial anoxemia produces in ganglion cells an abnormal state in which spontaneous neuronal activity is increased. This increase constitutes the epileptogenic factor. Cutting of an adhesion, opening of a cyst or removal of a tumor does not constitute adequate surgical therapy. The epileptogenic focus in the marginal partly involved gyri must also be removed. In 1941 Penfield and Erickson[2] published an analysis of all the patients who underwent cortical excision during a 10 year period, 1929 to 1939. One hundred and fifteen of these patients were followed one to 11 years; 43% were free from seizures or had one or two attacks; 26% considered themselves 50% improved; 9% were slightly helped, and 22% were not improved. In a later report Penfield and Steelman[3] presented an analysis of 76 patients operated on during the six year period 1939-1944, with one fatality, which was caused by an infected extradural hematoma and meningitis. Of the 75 patients followed, cortical excision was performed in 59 and craniotomy without excision in 16. Of the 59 patients who underwent cortical excision, 15 were completely free of seizures, 18 were almost completely free, eight were 50% improved, seven were only slightly improved and 11 felt that they had derived no benefit from the operation.

Removal of cortical tissue is justifiable in any area of the cortex except the arm and leg area of the precentral gyrus and in the essential speech area of the dominant hemisphere. The surgical treatment of focal epilepsy was made possible by the advances in the field of neurophysiology and the more accurate knowledge of cortical localization.

THE NURSE SHORTAGE

The present critical shortage of professional nurses is a matter of grave concern, in view of the indispensable role of the nurse in medical care. The shortage has arisen in part from increased demand for nursing service due to such factors as increased occupancy of available hospital beds, shorter working hours for nurses, expansion of public health work, and the increasing complexity of medical knowledge and techniques. Equally or more important factors, however, are the failure of approximately one-third of the students entering nursing schools to finish their course of training, and the fact that many registered nurses are not working at the profession. In 1949, the total number of professional registered nurses in the United States and territories was 506,050, but only 59% of these were actually engaged in nursing.[1] According to a recent release from the American Nursing Association, an additional 65,000 registered nurses are needed to render minimal nursing care to civilians, while an additional 3,000 nurses are required by the armed services. It is thus not surprising that nursing has been placed on the list of critical occupations by the United States Department of Labor.

[3] Penfield, W., and Steelman, H.: Treatment of Focal Epilepsy by Cortical Excision, Ann. Surg. 126:740 (Nov.) 1947.

[1] 1950 Facts About Nursing: A Statistical Summary, New York, American Nurses' Association, 1950.

In recent years, several studies have been undertaken to find ways to overcome the current shortage of nurses and to provide for additional needs that future developments in medicine will engender. The American Medical Association has taken an active role in these endeavors. In 1947 the Committee on Nursing was appointed to study nursing problems in the United States,[2] and in 1948 the American Medical Association joined with the American Hospital Association, the American Nurses Association and the National League of Nursing Education to form the Joint Commission for the Improvement of the Care of the Patient.[3]

Proposals for remedying the current shortage of nurses have in general centered around a more efficient use of nursing personnel, improved personnel practice, and the wider use of practical nurses and auxiliary workers. The institutional nurse, in particular, is all too often overburdened with clerical and housekeeping duties, which keep her from exercising the skills and knowledge gained during her period of training. In addition, many activities engaged in by the professional nurse could be adequately relegated to properly trained and supervised practical nurses and auxiliary workers, such as ward clerks, orderlies, and ward maids. Concerted efforts are being made not only to increase the training facilities for practical nurses but also to insure their integration into the nursing team. Already there are 318 or more schools of practical nursing in this country, with a total enrolment of 5,971,[4] a number which, however, falls far short of the demand. Emphasis, too, is being placed on the value of additional training for graduate nurses to enable them to undertake confidently the growing demands for nursing service in such fields as industry, school and college health clinics, home care, geriatrics, rehabilitation, and public health. Finally, it is becoming more and more evident that the adoption for the nursing profession of salaries, working hours, sick leave, vacations, and retirement provisions comparable to those of other occupations for women with equivalent education and training would do much to keep present nurses in the profession, to encourage retired nurses to return to active duty, and to stimulate the recruitment of new nurses.

SURGICAL THERAPY OF MITRAL INSUFFICIENCY

Dramatic advances have been made in recent years in the field of cardiac surgery. Great ingenuity has been shown in the devising of surgical technics for the correction of congenital and acquired anomalies of the heart. One particularly ingenious technic devised by Murray[1] for the surgical correction of mitral insufficiency has recently been modified by Bailey[2] with considerable success.

In 1938 Murray obtained significant improvement in surgically induced mitral regurgitation in dogs, and later[3] in man, by creating within the ventricle a new valve, of the sling or hammock type, which occluded the mitral orifice during ventricular systole and prevented the reflux of blood into the auricle. He constructed this valve by inserting a segment of peripheral vein reinforced with tendon entirely through the left ventricle, so that it formed a sling just below the mitral orifice. This graft was sutured to the outer surface of the ventricular wall at each end but was allowed to swing freely within the ventricle. During ventricular systole it was forced by the regurgitating current of blood against the patent mitral orifice, thus occluding it. During ventricular diastole the valve dropped away from the opening, permitting the flow of blood from the auricle into the ventricle. Such a valve survived for seven years without degeneration or loss of flexibility in one of Murray's dogs. Subsequently this procedure was employed in 10 patients with advanced mitral stenosis to correct the regurgitation that sometimes follows commissurotomy. Fairly satisfactory results were obtained in eight of these patients during an unspecified period of observation.

More recently Bailey and co-workers, in attempting to repeat Murray's experiments in animals with a somewhat modified technic, found that in all instances the free valve graft soon lost its resilience and became a shrunken fibrotic band, with consequent loss of efficiency as a valve. A similar experience was encountered when free grafts of pericardium were substituted for the vein grafts. These investigators concluded that free grafts of any tissue, deprived of their original blood and nerve supply, would prove unsatisfactory for long term correction of mitral insufficiency.

Their solution to this problem was the creation of a pedicled tube graft of pericardium, one end of which was left in situ while the other was freed and passed through the left ventricle to form the desired sling valve. Observations on animals over a period of months indicated that these pedicled grafts with intact blood supply functioned adequately and did not show a tendency to contract or become indurated. The method was therefore applied to seven patients with advanced mitral regurgitation. In two of these patients, who had both mitral stenosis and insufficiency, commissurotomy was performed at the same time to relieve the stenosis. The operation resulted in complete control of the regurgitation in three patients and in reduction of the regurgitation by at least 75% in three additional patients. In one patient the regurgitation was not controlled, probably because of improper placement of the valve. These early results are extremely encouraging. The future progress of these patients will be watched with great interest.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

As I stood before the House of Delegates in Atlantic City and repeated the oath of office of the President of the American Medical Association, I experienced one of the proudest moments of my life. The honor you have bestowed on me is accompanied by tremendous responsibility—a responsibility so great that no one can possibly carry it alone. Therefore, in my first message to you, I ask that you share this responsibility with me.

In thinking about the scope of our Association's activities over the past 104 years, it has become increasingly clear to me that our significant progress has been possible only through the combined efforts of individual physicians working together in their county, state, and national medical organizations. We can be justly proud of the progress we have made in advancing medicine, but we could accomplish far more if every physician in the United States were an active, interested member of his county medical society.

The American Medical Association has over 140,000 members, but numbers alone will not make us strong. The strength and success of the American Medical Association depends directly on the strength and success of its state and county medical societies. They in turn maintain their stature in direct proportion to the interest exhibited by the individual members on their roster.

Membership in a county medical society is a privilege that must be paid for with more than money. Dues are necessary, of course, but even more important is attendance at meetings, a willingness to participate in committee work, and, above all, a vision of the goals to be attained and a desire to work together with fellow physicians in reaching these goals.

The Principles of Medical Ethics sums up our membership obligations thus: "For the advancement of his profession, a physician should affiliate with medical societies and contribute his time, energy and means so that these societies may represent the ideals of the profession."

There are some who say that they do not have time to give to their county medical society because their practices are too demanding. In most instances this is only an excuse, the same story that too many physicians employ to avoid civic responsibilities of various kinds. I would remind such a physician that he is not as independent as he thinks; that many cultural, social, and political forces work constantly to change for better or for worse the conditions of his practice. Organized medicine is his bulwark against unfavorable forces, and it deserves his interest and support.

Another complaint that I have heard repeatedly is "The Society is run by a clique; why should I attend meetings?" While this may be true in isolated cases, the majority of societies welcome interested and willing workers. The same criticism is voiced of our state medical societies and of the American Medical Association. I know of no organizations in America that are run on a more democratic basis than those of physicians. Perhaps it does seem that the same persons are active and influential in many medical organizations. If such be the case, you can be sure that they have developed their interest and leadership at the cost of attending meetings and actively participating in the business of the society.

Recently there have been a few physicians who have resigned from the American Medical Association because they did not agree with some of its policies. I wonder if these same persons consider giving up their American citizenship when they disagree with the administration in power? This is admittedly a strong comparison, but it seems infinitely more logical to me for those of our members who disagree with some American Medical Association policies to exercise their membership privileges to the fullest in the hope of effecting a change in the policies they oppose, rather than taking the sterile course of resigning.

Why is it so important to have strong medical organizations? Because, as in other areas of society, groups can accomplish much more than individuals. Most of you are familiar with the excellent group accomplishments of county medical societies. They have successfully set up night and emergency telephone-answering systems, established group malpractice plans, furnished health information to newspapers and radio stations, operated grievance committees to hear and settle patient complaints, organized community health councils, spearheaded hospital drives, and many, many other community service projects in addition to their scientific programs. These activities would be virtually impossible for any individual to conduct.

In the same way, the American Medical Association, on the national level, performs public service functions and professional service functions that would be difficult for any individual or local group to carry out. It is easy for most physicians to understand the importance of county society and state society membership, but the American Medical Association seems far removed from the individual M.D. Actually, its many activities touch the lives of you and your patients almost daily.

A year ago, after my selection as President-Elect, I paid a five-day visit to the headquarters office of the American Medical Association in Chicago for the express purpose of learning all I could about the workings of the Association. They were among the most enlightening and valuable days that I have ever spent. Even though I had been active in medical organization affairs for many years and had served in the A. M. A. House of Delegates and on the Campaign Coordinating Committee, I was amazed at the scope of the Association's activities. Some council or bureau of the Association is concerned with every aspect of medicine and health. I was impressed, too, with the spirit of service which pervades the doctors and laymen who make up the headquarters staff. When I completed my visit, I left with a feeling of deep pride that I was a member of this great organization. I left also with an optimistic heart, feeling that much could be accomplished in the future. Because most physicians do not, or cannot, take the time to spend five days at the Association headquarters, I plan to devote a number of my President's Pages to describing some of the activities I observed on this visit. Briefly, I shall discuss the scientific activities of the Association, including the Division of Therapy and Research, the scientific publications and the two annual scientific meetings. I also plan to tell you what I have learned of the American Medical Association's activities in the socioeconomic fields of medicine—health insurance, indigent care, the problems of the aged and chronically ill, rural health, industrial health, and so forth. If you will come with me on this monthly word-visit to our Association headquarters, I believe you too will leave with a new pride in our profession and what it is attempting to do through its national association.

So far, in discussing the advantages of strong medical organizations, I have dwelt largely on their day-to-day scientific and public service contributions. There is another role that medical organizations play which is perhaps even more important—their role as the voice of the profession in public affairs and matters of ethics.

You are all well aware of the fight which our profession has been forced to wage for the last few years in order to preserve the freedom of medical practice in this country. There is no doubt that this battle would have been far more difficult, if not impossible, to win if we had not been organized on a county, state, and national basis. The price of liberty is vigilance, and we must remain on guard. But our efforts have been successful to the extent that we have won a breathing space wherein we may turn our attention to weak spots within our own ranks.

The general public thinks of the medical profession in terms of the services that are rendered by each physician. When one of our colleagues violates the Principles of Ethics, he jeopardizes not only his own position but that of the entire profession. The vast majority of physicians are ethical and take great pride in the quality of their service. But you and I know that there are a few who capitalize on medicine's high professional reputation for their own selfish ends.

It is one of the primary responsibilities of medical associations to uphold the high ethical standards of the profession. This is one of the main reasons why such organizations must be strong and vigorous. No medical association can ever expect to capture the respect of the people unless it makes a real effort to purge from its ranks those who choose to ignore the principles of ethics which govern its members.

For this purpose, if for no other, I urge you most sincerely to take an active part in your county medical society. A strong, courageous society can be a spiritual leader. It is only through medical organizations that unworthy physicians can be successfully disciplined. Only a medical association can deal with those who overcharge, who refuse service, who put income and personal comfort above their duty to their patients.

Self-discipline is a difficult challenge, but if we are to protect the medical profession from those who would destroy it, we must meet this challenge successfully.

John W. Cline, M.D., San Francisco.

ORGANIZATION SECTION

THE ATLANTIC CITY SESSION

On June 15, the 100th annual session of the American Medical Association came to a successful conclusion in Atlantic City. Acknowledged as this country's largest and most comprehensive medical meeting, the session drew more than 12,000 physicians to the city's huge convention hall and to the conference rooms of five of the largest hotels. Included in this registration were visitors from 46 foreign countries. As usual the scope of the session was tremendous. In a program arranged by the American Medical Association's Council on Scientific Assembly, 358 papers on many aspects of medicine were presented. At the same time 297 scientific exhibits occupying the entire lower level of the block-long convention hall and 350 technical exhibits covering an equivalent area on the main floor of the hall competed for the attention of those attending the convention. Added to this wealth of material were 37 medical motion pictures shown daily in two separate projection rooms and 17 color television demonstrations of surgical and medical procedures transmitted on a closed circuit from the Atlantic City Hospital.

SCIENTIFIC EXHIBITS

Unstinted praise of those attending this year's meeting went to the scientific exhibit. Here, grouped together according to the various medical specialties, were row after row of well-executed exhibits demonstrating vividly recent medical advances in each field or summarizing available knowledge on subjects of current interest. The enthusiasm of the exhibitors and the searching questions of the visitors made this one of the most valuable postgraduate educational features of the entire annual session. There were so many excellent displays that it was difficult for the committee on awards to select the most outstanding.

The Exhibits Committee on Awards made three Gold Medal, two Silver Medal, and two Bronze Medal presentations for the highest honors in Group I of the Scientific Exhibit—exhibits of individual investigations which are judged on the basis of originality and excellence of presentation. Recipients of one Gold Medal are Robert P. Glover, Charles P. Bailey, and Thomas J. E. O'Neill, Hahnemann Medical College, Hahnemann Hospital, and Episcopal Hospital, Philadelphia, for the exhibit on intracardiac surgery for acquired and congenital heart disease. The other Group I Gold Medal went to Willis J. Potts, William L. Riker and Robert DeBord, Children's Memorial Hospital, Chicago, for the exhibit on surgery for congenital heart disease. Group I Silver Medal winners are David Cayer and W. E. Cornatzer, Bowman Gray School of Medicine, Winston-Salem, N. C., for the exhibit on the role of lipotropic agents in liver disease—a study of phospholipid synthesis with the use of radiophosphorus. In the same group, the Bronze Medal went to William P. Boger, Walter V. Mattecci, Nelson H. Schimmel, and Harrison F. Flippin, Philadelphia General Hospital, Philadelphia, for the exhibit on benemid—its influence on paraaminosalicylic acid, penicillin, and other antibiotics.

The Gold Medal in Group II—exhibits that do not exemplify purely experimental studies but are judged on the basis of excellence of presentation—was awarded to Walter W. Williams, Springfield Hospital, Springfield, Mass., and Irving F. Stein and Melvin R. Cohen, Michael Reese Hospital, Chicago, for the exhibit on fertility and sterility—diagnosis and prognostic procedure. Silver Medal winners in that division were C. Stuart Welch and William Dameshek, Pratt Diagnostic Clinic, New England Center Hospital, Boston, for the exhibit on surgery of the spleen. The Group II Bronze Medal went to Robert R. Linton, Chester M. Jones, John J. Cranley Jr., James L. Buchanan, Daniel S. Ellis, and Arthur French, Brookline, Mass., for the exhibit on the surgical treatment of bleeding esophageal varices (portal hypertension).

Also popular were the daily clinical demonstrations on the management of fractures, the daily demonstrations of fresh pathological specimens and the symposiums on obesity, nutrition, and health. Honorable mention was given to the special exhibits on diabetes and on noise in industry.

TECHNICAL EXHIBITS

The technical exposition was the largest in the history of American Medical Association sessions. Over 2,000 representatives of 350 commercial firms demonstrated new drugs, diagnostic and therapeutic instruments, medical books, dietary products, and various appliances for the handicapped. Questions about the use of new therapeutic agents were answered, and samples and informative literature were distributed. Much interest was shown in such new instruments and equipment as the Norment hysteroscope, which permits direct visualization and biopsy of the interior of the uterus; the Berman electronic metal locator and the Kirby-Thurston electro-acoustic locator for detecting foreign bodies or gallstones; portable electrocardiographs; endoscopic cameras; self-adhering plastic disposable "Scotch" surgical drapes, and many compact laboratory diagnostic kits. Each year the elaborate "window dressing" of many of the commercial exhibits lends to this part of the session a holiday air that is sometimes misinterpreted by lay visitors and representatives of the press. Seeing this exhibit first because of its central location, they sometimes carry away the impression that this "county fair" atmosphere is the keynote of the entire session. Fortunately those who take the trouble to listen to the earnest exchange of ideas between the users and the producers of these medical goods or to attend the scientific exhibits and section meetings are soon unburdened of this completely erroneous impression. The majority of physicians leave the technical exhibit with new knowledge of technical advances, and the commercial representatives with new ideas for the improvement of their products, both to the ultimate benefit of the patient.

TELEVISION AND FILMS

A capacity audience was present continuously in the medical television exhibit. Here the crowd of visitors was taken by the television camera directly to the operating table or bedside, where experts demonstrated in full color a variety of surgical and medical procedures. Televised operations included appendectomy, thyroidectomy, pneumonectomy and sympathectomy. Angiography, sympathetic nerve block, and techniques of neurologic and dermatologic diagnosis were also demonstrated. The program was an unqualified success, and with one exception it proceeded without interruption. The interruption occurred when a normal male infant refused to be born on schedule, at 11:35 A. M. on Thursday. A good-natured crowd of 1,500 waited for two hours and 15 minutes for this debut.

The daily showings of the 37 scientific moving pictures likewise proved popular. Films on such topics as coarctation of the aorta, carcinoma of the rectum, corticotrophin (ACTH) in human disease, and treatment of poliomyelitis provided further postgraduate instruction for visiting physicians.

SECTION MEETINGS

The general scientific meetings held during the first two days in the grand ballroom of the convention hall were well attended. Outstanding speakers presented résumés of current knowledge in a variety of fields of general interest including medical aspects of atomic energy, blood substitutes in the treatment of shock, cardiovascular surgery, the newer drugs in the treatment of the anemias and tuberculosis, and the ever present problems of obesity, arthritis, acute gallbladder disease, thyroid disease, and personal maladjustment. In one of these meetings, Dr. Charles Huggins of Chicago reported on the favorable effects of bilateral adrenalectomy in far-advanced carcinoma of the prostate.

During the next three days, the 20 special sections of the scientific assembly held their meetings in the convention hall and in nearby hotels. The more than 350 papers presented reported the results of original investigative work in each of the medical specialties or brought the profession up to date on problems of particular interest. The newly created Session on Military Medicine was declared by Dr. Richard L. Meiling, chairman of the Armed Forces Medical Policy Council, to be an important instrument in the increasingly necessary liaison between physicians in civilian and military medicine. The urgent need for making available to each type of medicine the rapid advances being made in the other was stressed. As Captain E. R. Herring of the United States Navy so aptly stated, the war may at any time be deposited on the doorstep of the civilian doctor. After giving a dramatic account of combat medical experience in Korea, Captain Herring made an impassioned plea for the thorough training of all civilian doctors and medical students in the care of mass casualties before it is too late. Subsequent papers on the program continued this theme with discussions of the prevention and management of radiation injuries and reports on the results obtained with the open air exposure method of treating burns. Both Dr. Meiling and Major Gen. Harry G. Armstrong, Surgeon General of the United States Air Force, stressed the great importance of air evacuation of the wounded, and this was discussed in further detail by other speakers. It was pointed out that no American soldier is now more than 36 hours away from a hospital in continental United States, an important factor in the morale and recovery of the wounded. The rapidity of air transport also makes it unnecessary to overstaff overseas medical units during relatively quiescent periods since emergency medical personnel can be flown directly to the area of greatest need within 24 to 36 hours.

In the Section on Surgery success was reported with another method for the local treatment of burns. Drs. R. M. Curtis, J. H. Brewer, and I. W. Rose Jr., of Baltimore, found that a partially hydrolyzed casein gel covered with zinc-acetate-impregnated gauze formed a semipermeable membrane over the burned area that immobilized damaged tissue, prevented superficial protein loss, relieved pain, and minimized shock and infection. In the same section the results of the surgical treatment of mitral stenosis by commissurotomy were described by Drs. T. J. E. O'Neill, R. P. Glover, and C. P. Bailey, of Philadelphia. The operation, performed on more than 130 patients, yielded subjective and objective improvement in nearly all who survived. Excessive mitral regurgitation occurred in only a few cases.

Several investigators in the Section of Anesthesia reported good results with the use of the newer plasma substitutes, such as dextran, polyvinyl pyrrolidine (P. V. P.), and gelatin, in the restoration of blood volume in shock. These materials, which are useful as substitutes for plasma but not for whole blood, are now being stock-piled for use in civilian emergencies.

Extensive experience with corticotrophin (ACTH) was summarized in several sections in papers dealing with its use in postoperative complications, in ulcerative colitis, in rheumatoid arthritis and in various allergic, dermatologic, neurologic, and ocular conditions. Among the interesting sidelights in these presentations was the observation by Dr. Joseph Kirsner of Chicago that an occasional patient with ulcerative colitis who did not respond to intramuscularly administered corticotrophin showed a remission when given the drug intravenously. Dr. Robert Kierland of Rochester, Minn., reported the dramatic resolution of syphilitic interstitial keratitis following the application of 1% or 2% cortisone in aqueous solution to the affected eye.

In an outstanding symposium on arteriosclerosis and hypertension presented before a joint meeting of the Section on Internal Medicine and the Section on Experimental Medicine and Therapeutics, Dr. Ancel Keys of Minneapolis summarized the evidence on the relationship between cholesterol and atherosclerosis. He concluded that in clinically normal persons serum cholesterol is independent of dietary variations within the range of 200 to 800 mg. of cholesterol daily. If enormous amounts of cholesterol are ingested, hypercholesteremia is slowly produced, while cholesterol-free diets produce a decrease in serum cholesterol only if they are also free of fat. Animal and vegetable fats are equivalent in this respect. Diets low in fat, with 500 mg. cholesterol daily, also produce marked declines in serum cholesterol. Serum levels of total cholesterol and of abnormal protein-cholesterol macromolecules ("G") parallel each other and seem to predispose to the development of atherosclerosis. Total cholesterol values provide an index as satisfactory as or better than "G" values in predicting atherosclerosis.

In the same symposium, Dr. Irving Page of Cleveland discussed the current treatment of hypertension, emphasizing the multiple causation of this condition and suggesting a correct diagnosis as the first step in treatment. In essential hypertension he advised the establishment of a firm doctor-patient relationship and the institution of general physical and mental hygienic measures, supplemented by sedation. While not placing too great reliance on hypotensive drugs, he reported some success with one of them, L-hydrazinophthalozine (C-5968). In his experience, only 20% of the hypertensive population respond to a low salt diet and only rigidly selected patients respond to sympathectomy. Adrenalectomy was regarded as a last resort, while intravenous pyrogen therapy was found to be helpful in malignant hypertension provided renal failure was not severe. In addition to the papers mentioned, a number of other excellent studies on the subject of hypertension and atherosclerosis were presented in this and other sections.

The physiologic, pathologic, psychiatric, and industrial aspects of aging were considered in several sections, and the growing role of physical medicine in the rehabilitation of amputees, neuro-psychiatric patients and the chronically ill was stressed in the Section on Physical Medicine and Rehabilitation.

The successful use of fat emulsion in intravenous alimentation was reported by Drs. B. Van Itallie and J. Stare, of Boston, in the Section on Experimental Medicine and Therapeutics. A 15% homogenized fat emulsion providing 1,600 calories per liter was found useful as a caloric supplement in preoperative or convalescent patients unable to take adequate calories by mouth. Since the fat is used for energy, it spares endogenous protein and reverses the negative nitrogen and potassium balances due to inadequate caloric intake.

The usefulness of intravenously administered saccharated oxide of iron in the treatment of anemia was confirmed by Dr. C. C. Briscoe of Philadelphia in 100 obstetric and gynecologic patients.

In separate studies on the epidemiology of infectious hepatitis, Dr. R. Capps of Chicago and Drs. J. Stokes Jr., M. E. Drake, J. Farquhar, and M. C. Blanchard, of Philadelphia and Columbus, Ga., found that the virus of this disease may produce epidemics of infantile diarrhea without jaundice. The severity of the disease as well as the occurrence of jaundice appears to vary directly with the age of the patient. In the epidemic described by Capps, careful washing of the hands on the part of the student nurses prevented their contracting the disease from the affected infants. The epidemiologic value of the specific skin test employing inactivated virus was demonstrated in both studies as was the prophylactic value of gamma globulin.

In the Section on Radiology, Drs. I. Steinberg and T. Dotter, of New York, demonstrated the diagnostic and prognostic value of angiocardiography in 100 cases of lung cancer. Evidence of vascular abnormality as a result of the tumor was seen in 87% of the cases, and its location often aided in the determination of the operability of the lesion. It is predicted that the use of angiocardiography in patients suspected of carcinoma of the lung will become routine.

OTHER AWARDS

In addition to the scientific meetings and exhibits, the session included the presentation of a number of awards for notable contributions in various branches of medicine. The Distinguished Service Medal of the House of Delegates went to Dr. Allen O. Whipple of New York for his outstanding contributions in the field of operative surgery. The Joseph Goldberger Award in clinical nutrition, consisting of a gold medal and a $1,000 cash prize, was presented to Dr. Fuller Albright of Boston. Drs. Philip Levine and Alexander S. Wiener, two of the nation's most distinguished hematologists, received the $5,000 Passano Foundation Award for 1951, while Drs. Philip S. Hench and Edward C. Kendall were recipients of the $10,000 Dr. C. C. Criss Award for outstanding contributions in the fields of health and safety.

PRESS AND RADIO

That the activities of the annual session were of interest not only to physicians is indicated by the fact that 78 science writers, representing 58 newspapers, wire services, magazines, and publishing houses, were present to cover the scientific presentations and the actions of the A. M. A. House of Delegates. In addition, numerous radio broadcasts originated at Convention Hall and 20 special medical programs were recorded for subsequent broadcast to English-speaking countries by the Voice of America.

HOUSE OF DELEGATES AND BOARD OF TRUSTEES

For the first time in its history the House of Delegates seated two medical students. These student delegates were Warren R. Mullen of Jackson, Mich., and Harry W. Sandberg, Moline, Ill., who are president and vice president, respectively, of the Student American Medical Association, the objectives of which, so far, have been actively supported by societies organized in 40 medical schools.

Dave Beck of Seattle, executive vice president of the International Brotherhood of Teamsters, addressed the House of Delegates and other officers of the American Medical Association at a dinner meeting given by the Medical Society of New Jersey. Mr. Beck's paper, "Government Medicine—Danger Ahead," appears elsewhere in this issue of The Journal. The broadcast was carried by about 100 stations of the American Broadcasting Company and originated from station WMID in Atlantic City. There was no doubt in anyone's mind concerning the forcefulness of Mr. Beck's message as he expressed support of the physicians' campaign against compulsory health insurance and opposition to government-regulated medical care.

The announcement of the Board of Trustees that it plans to appoint a committee of prominent laymen representing industry, labor, education, agriculture, the bar, and the clergy, from which to seek advice in matters of medical care and from which it can obtain the viewpoint of the general public, was received with enthusiastic response. Several weeks may elapse before the members of the new committee can be announced, but the membership will be free of persons who are engaged in politics but who are so outstanding that their opinions will receive unquestioned respect.

Included in the officers elected were Louis H. Bauer of Hempstead, N. Y., as President-Elect; Oscar B. Hunter of Washington, D. C., Vice President; David B. Allman, Atlantic City, to fill Dr. Bauer's term on the Board of Trustees; Walter B. Martin of Norfolk, Va., to succeed himself as a member of the Board of Trustees; and George F. Lull, Chicago; J. J. Moore, Chicago; F. F. Borzell, Philadelphia, and James R. Reuling, Bayside, N. Y., to succeed themselves as, respectively, Secretary, Treasurer, Speaker, and Vice Speaker of the House of Delegates. Samuel P. Newman of Denver was elected to succeed himself as a member of the Council on Scientific Assembly, and F. D. Murphy, Kansas City, to succeed William S. Middleton as a member of the Council on Medical Education and Hospitals. The following members were elected to a Permanent Committee on Constitution and By-Laws: Louis A. Buie, Rochester, Minn., term to expire June, 1956; Britton E. Pickett, June, 1955; Floyd S. Winslow, June, 1954; Stanley H. Osborn, June, 1953, and James S. Stevenson, June, 1952. Henry B. Mulholland and J. D. McCarthy were elected to succeed themselves as members of the Council on Medical Service.

The 1951 Clinical Session will be held in Los Angeles, December 4-7. The A. M. A. meetings which will be held between now and the end of 1954 are scheduled as follows: December 4-7, 1951, Los Angeles; June 9-13, 1952, Chicago; Dec. 1-5, 1952, Denver; June 1-5, 1953, New York City; Dec. 1-4, 1953, Saint Louis; June, 1954, San Francisco; December, 1954, Miami.

The Council on Medical Service of the American Medical Association has maintained a physician placement service through which communities have been assisted in obtaining the services of a physician. The Board of Trustees at the Atlantic City meeting urged expanding the Association's activities in this field and the further development of physician placement services in state medical societies. The Board will give support to this program by financing it to the degree demonstrated to be necessary.

Several resolutions were introduced concerning membership in the American Medical Association and the abandonment of Fellowship. The Reference Committee on Amendments to the Constitution and By-Laws approved in principle the resolutions concerning membership but believed that abandonment of Fellowship deserved further study. The Committee recommended that this subject be referred to the standing committee of the House on Constitution and By-Laws with instructions to prepare such changes in the Constitution and By-Laws, in consultation with the Board of Trustees, as may be necessary to carry out the recommendations. These changes are to be reported to the House of Delegates at the next meeting.

The House also considered another change in the Constitution which must lay over until the next session. At this time a change in the By-Laws will be necessary to permit the five immediate past presidents of the American Medical Association to become members of the House of Delegates for five years with the right to vote. The composition of the Board of Trustees also was changed to include the president and president-elect as members. Thus, in addition to the nine elected members, the Board of Trustees includes the President and President-Elect.

Further consideration was given to the payment of dues for members in the American Medical Association. The 1952 dues of the Association were set at $25, this to include subscription to The Journal. Annual dues are prescribed for the ensuing calendar year in an amount recommended by the Board of Trustees and approved by the House of Delegates. Every active member pays his annual dues to his constituent association for transmittal to the secretary of the American Medical Association. The Board of Trustees may excuse a member from payment of dues for the following reasons, provided he is wholly or partially excused from paying local and state dues: 1. Members on whom the payment of dues would work a financial hardship. This fact must be certified to by the Secretary of the member's component society. 2. Members retired from active practice. 3. Interns and residents during the first five years following graduation, except that the time spent in the military service may be excluded in calculating the five-year limit. 4. A member temporarily in the Armed Forces. Dues will be remitted and pro-rated January 1 or July 1 following the date of the member's entrance into military service.

Members over 70 years of age may be excused, on request, from the payment of American Medical Association dues, regardless of local dues exemptions.

The firm of Whitaker & Baxter has been retained on a part time basis for 1952.

A lengthy and informative report submitted by the Committee on Blood Banks carried four recommendations of much interest to physicians: (1) that physicians and their families be urged to participate as donors for defense and civilian defense purposes, (2) that there continue to be developed state blood committees performing the functions above outlined, (3) that Congress be reminded of the urgent need for appropriations for reasonable federal stores of plasma and equipment for civilian defense, and (4) that physicians using blood recognize their responsibility in replacement from families and friends of patients.

The House adopted a resolution in which the American Medical Association requests Congress to make a thorough investigation of the school system in the United States with particular reference to the teachers and authors of textbooks advocating the overthrow of the American system of free enterprise by the infiltration of un-American policies of collectivism. A copy of this resolution was ordered sent to the President, Vice President and members of the United States Senate and House of Representatives.

The House also adopted a resolution which voiced protest against the use of tax funds provided from the federal government for postgraduate courses in medicine. This resolution introduced by the Arkansas delegation urged the adoption of efforts to eliminate from future budgets the expense of conducting courses in postgraduate work for the medical profession, the Arkansas delegation asserting that it is the desire of the medical profession of Arkansas to pay personally such fees for postgraduate instruction as is received in the future.

The House adopted a recommendation for the creation of a national joint commission on accreditation of hospitals by the American College of Physicians, American College of Surgeons, American Hospital Association, and the American Medical Association. The American College of Surgeons for 25 or more years has administered a hospital standardization program. Because of the expense of the project, plans were proposed whereby several bodies would participate. A report and recommendations for the various interested groups has been proposed by committees from each organization. The joint findings will be acted on by the four associations before they can be accepted as the guiding principles for a national joint commission on accreditation of hospitals.

At the request of the Council on National Emergency Medical Service, the Board of Trustees agreed to undertake a study immediately for the purpose of making recommendations and meeting the medical problems which may arise with the legislation pertaining to the universal military training act in order to best serve the medical and health needs of the armed forces and of the civilian population of this nation. Complex and far-reaching medical implications are present in this Act.

An invitation was accepted by the Board of Trustees to meet with the officers of the American Hospital Association for discussion of hospital-physician relations.

The Board also has authorized the appointment of a Committee on Nervous and Mental Diseases since the American Medical Association does not have a committee on mental health.

The Board approved the appointment of an Advisory Committee to the Council on Medical Education and Hospitals, to be composed of leaders in the field of education, practice and hospital administration, to study the problem of discrepancies between the number of internships offered and the number of available candidates. The Board has appropriated sufficient funds to permit the committee to function.

OTHER ACTIVITIES

Senator Robert M. Nixon of California, speaking at the Annual Conference of Presidents and Other Officers of State Medical Associations, said that physicians should become more interested in all types of political issues. At the same time, he commended the medical profession for its leadership in urging voluntary financial aid to medical schools. Dr. Julian Price of South Carolina was succeeded by Dr. W. Andrew Bunten of Cheyenne, Wyo., as president of this conference. Dr. J. Stanley Kenney of New York City is president-elect.

One of the highlights of the meetings of the Woman's Auxiliary to the American Medical Association was the presentation of a check for $10,000 to Dr. Elmer L. Henderson for the American Medical Education Foundation. The president of this more than 50,000 membership organization is Mrs. Harold F. Wahlquist of St. Paul, and the president-elect is Mrs. Ralph Eusden of Long Beach, Calif.

Another announcement of a large contribution to the American Medical Education Foundation was from the Board of Chancellors of the American College of Radiology, which voted to give $2,000 to this fund.

In the 35th annual tournament of the American Medical Golfing Association, V. W. Guidice, Ridgewood, N. J., and Harold Sargin, Cleveland, took the honors. More than 260 physicians turned out for this event.

Medical artists again exhibited their handiwork at an American Medical Association meeting. The exhibit included painting, sculpturing, photography, needlework, ceramics, jewelry, and other forms of artistic effort. There were more than 700 entries in 18 different media. The American Medical Art Association, which has 4,000 members in the United States, Canada, and Hawaii, now has as its sponsors the J. Henry Helser & Co., investment managers on the Pacific coast. This company provided approximately 200 trophies for exhibit awards. All entries will be displayed at Macy's department store in New York City from June 25 to July 5.

BROAD MEDICAL INTERESTS

Evidence of the interest of the profession in the affairs of the Association was seen in the large number of visitors attending the meetings of the House of Delegates and at the room-filled Reference Committee meetings. Many delegates and other members of the Association complained that it was impossible for them to attend all the meetings that interested them. This complaint was in the nature of a compliment, however, because it showed the broad field of interest of the House and of the various councils and committees that were meeting. From 8 o'clock in the morning until late in the evening, various groups were constantly in session. Except for executive sessions, the doors were open to those who wished to enter into any of the discussions and to those who merely wanted to listen. Whether one attended the scientific demonstrations, listened to the lectures, or participated in the meetings of the House of Delegates and of the councils and committees, such as the Judicial Council, Council on Medical Service, Council on National Emergency Medical Service, Council on Medical Education and Hospitals, and Advisory Committee of the State Journal Advertising Bureau, he could see on all sides evidence of great activity in the medical profession. Thus the reports the delegates are carrying back to their state societies will not in any way be regarded as reflecting limitation in scope of medical interests. Instead they will show how physicians today are more determined than ever to meet their responsibilities as citizens and practitioners.

GOVERNMENT MEDICINE—DANGER AHEAD!

DAVE BECK

Executive Vice President, International Brotherhood of Teamsters (AFL).

One of the most critical problems of our time is adequate medical care for all of our people. The real crux—the heart of the matter is: how can we bring adequate medical care within the economic grasp of our citizens?

That this is the problem few will disagree.

But the road to final solution is not through socializing the medical profession.

Our job as American citizens is to meet this challenge of medical care. We cannot meet it with explosive propaganda aimed at destroying the system of free enterprise in the profession of medicine.

The answer to the problem of medical care will not be found in any political panacea or through the development of a super bureaucracy. The answer to the problem will be neither simple nor easy, but it will be found within the framework of our present economic system and our present constitutional safeguards.

GOVERNMENT MEDICINE CANNOT BE TOLERATED

The answer as proposed by advocates of Government-controlled medicine is contrary to our economic structure and goes beyond our traditional guarantees. Any system which proposes

---

Read at a dinner meeting given by the Medical Society of New Jersey in honor of the officers of the American Medical Association and members of the House of Delegates during the 100th Annual Session of the American Medical Association, June 11, 1951, Atlantic City, N. J.

such modifications in our way of living and doing things would lead to a dangerous socialistic trend and cannot be tolerated. Such a system would destroy our liberty.

Patrick Henry 175 years ago said that "eternal vigilance is the price of liberty." It is incumbent upon you members of the American Medical Association to be eternally vigilant against panaceas and bureaucracies which would socialize your profession and destroy initiative and freedom not only among your associates today but for generations to come.

The doctor in America has won his present high place in the hearts and spirits of our people through his study, toil, sacrifice and service. The long story of medical progress is written in thrilling chapters of service to humanity—by unknown research workers in the laboratories, by general practitioners in city and country, by the specialists and surgeons who devote their skills to the art of healing.

You have earned the respect of your fellow countrymen over and over through the work you have done on Main Street, in our great cities, on the battlefield, in our hospitals and in the classrooms.

MEDICAL PROGRESS—THE PRODUCT OF INDIVIDUAL INITIATIVE

The medical profession has grown to its present high estate under our system of democratic freedoms. The opportunity to meet the challenges of disease and death has been taken by the doctors using the weapons of science, truth and skill—all wielded within the framework of a free society. That freedom must be preserved. For in that freedom medicine has grown and will continue to grow if there is no interference with individual initiative. The progress of American medicine must not be blocked by the impediments of an uncertain and clumsy bureaucracy.

I have seen the experience of State Medicine in other countries. I have traveled abroad extensively in recent years and have had the opportunity to see at first hand the failure of Socialized Medicine. It is my opinion that if the peoples of any country want Socialism or Communism, that is their business and their decision. We don't want either in America!

The answer lies in Voluntary medical programs—prepaid medical plans. The only question is: how best can we perfect these programs?

We have made progress—and great progress. There has been an ever-increasing consciousness on the part of the American people of the tremendous value and necessity for maximum protection against unforeseen medical costs which arise out of illness or accident both for the wage earner and for his entire family. That a new National health structure is in evolution few will deny.

LABOR UNIONS IN FOREFRONT OF VOLUNTARY HEALTH INSURANCE DEVELOPMENT

There are now more than 72 million people insured under one or another of the prepaid medical plans. Today one of the outstanding jobs in this field is being performed by the labor unions.

Millions of people are covered by welfare plans as a result of labor negotiations during the last two years. An excellent example of this will be found in the Western Conference of Teamsters which includes the 11 Western States. Since July, 1950, we have provided medical coverage for upwards of 180,000 members and their families. The sole purpose of our plan is to protect our members by seeing that funds are available to pay for medical care when the occasion arises. Free choice of doctors is the paramount feature of our plan.

I would never, under any circumstances, be a party to an arrangement of any kind whatsoever, which would deny to any man the right to choose the doctor he wishes to treat him in his hour of need and suffering. Nor would I refuse any man the right to name the medical practitioner in whose hands and skill he has the confidence to place the health, perhaps the lives, of his loved ones.

FREE CHOICE OF DOCTORS, HOSPITALS IS ESSENTIAL

I believe that a tremendous responsibility rests upon all of us to see that we continue and expand and improve our Voluntary medical care program. No one can deny that the Voluntary plans are doing a magnificent job, but there is still much to do. I do not emphasize commercial health and accident coverage, or the Blue Shield or Blue Cross Plans, but any sound plan which is on a Voluntary basis, allowing free choice of doctors and hospitalization. I have noted, too, that the AMA has not recommended one over another, but believes in healthy competition between them. It is on the development of these plans that we must have the maximum cooperation from the medical profession.

This system of Voluntary health care is making a great record in this country. Let us continue the Voluntary way of doing things in America—it is our best protection against any compulsory way. It is compulsion and interference with our individual freedom and initiative which lead to State control—dictatorship, Fascism, Communism. We want none of these in America. We will not permit any of these to take root in the profession of medicine.

I say to the American Medical Association: you have every right in the world to protect the interest of your members and to fight for the preservation of your profession. As you well know, I believe in unions. And you doctors have a pretty good union. I believe in organization—it leads to mutual exchange of ideas, knowledge and information and mutual protection. I believe in it for the laboring man and I believe in it for the doctor. I say to the doctor: join and support your organizations—locally and Nationally—and continue the fight for high medical standards, for your own self-preservation and against this monstrous evil of socialization. More credit and glory to you!

ONLY UNREGIMENTED MEDICINE CAN SERVE PUBLIC EFFECTIVELY

I am convinced, and American experience proves it beyond a doubt, that the medical profession can advance to its highest point of attainment in the service to the public only if it remains free and untrammelled. I am positive that the doctor, in the face of public need and in pursuit of the high ideals of his profession, will make use of his individual freedom, and of his individual ability and initiative, to advance as far as intelligence and skill will permit. He cannot attain those heights of professional achievement under a socialized or regimented system of medicine.

The crux of the issue, I repeat is: how can we bring adequate medical care within the economic grasp of every citizen in the land? The other phases of the medical problem can be more readily solved—wider distribution of doctors, more clinics, more hospitals, more medical research, more preventive medicine—all of these are important and programs for their solution are progressing rapidly.

This problem of bringing medical care to all of the citizens of this country is one of the most pressing, and at the same time, most troublesome problems we have ever faced. It is difficult to solve because it involves two fundamental concepts which some say cannot be reconciled: first, free enterprise, the right of the doctor to practice his profession as a free man in a free society, and—second, the right of the people of the Nation to have available to them and within their economic reach, all of the medical care and attention which are necessary to keep them in the highest state of health known to medical science.

NO CONFLICT BETWEEN FREE ENTERPRISE AND ADEQUATE HEALTH CARE

I deny that there is any insoluble conflict between these two concepts. We must reconcile them to solve our problem. We must find some plan whereby free enterprise is preserved and wherein the health of the Nation is safeguarded and strengthened. Socialized or Federalized medicine is not the answer. The Voluntary way is the American way.

I believe in the maximum of liberty for all Americans, and in their right to rise to high levels of accomplishment, through their own skill, initiative and intelligence. I say that we have built this great Nation through individual initiative and intelligence. We have made mistakes in the past—we will make them in the future, but let us never make the mistake of socializing the medical profession. We have been born as a great people and we will continue to thrive as a great people only under a system of free enterprise—free for the business man, free for labor, free for the doctors and free for all of our people.

MEDICAL LEGISLATION

STATE

California

Bills Introduced.—H. R. 195, proposes that the Assembly Interim Committee on Finance and Insurance be directed to study and analyse all facts relating to the furnishing of **prepaid medical, surgical, hospital and other related services,** especially by unlicensed, unregulated and nonprofessional persons and organizations. A. 2673, to amend the Business and Professions Code, proposes to permit the use of the **injunctive process** to restrain violation of such code. A. 2924, to amend the **chiropractic** act, proposes, among other things, to define unprofessional conduct as the procuring, aiding, or abetting in the procuring of criminal abortions; the paying for steering patients into one's office; obtaining a fee on the assurance that a manifestly incurable disease will be made entirely well; the wilful betrayal of professional secrets of a patient to the detriment of such patient; chiropractic advertising which is untrue or misleading; conviction of any offense involving moral turpitude; wilful neglect of a patient in a critical condition. S. 731, to amend the health and safety *code, proposes to require hospitals to keep a record of the administration* of **hypnotic drugs,** including the amount given, the type, the date, and the name and address of the person to whom administered.

Bill Enacted.—A. 3412, was approved June 1, 1951. It amends the Revenue and Taxation Code by specifically providing that the producers of **X-ray films** for the purpose of diagnosis are the consumers of materials and supplies used in the production thereof.

Connecticut

Bill Enacted.—S. 48, has become Public Act No. 78 of the Acts of 1951. It provides for the creation of a **board of examiners of hypertrichologists** *and defines hypertrichology as the removal of superfluous hair by electrical* or other methods approved by the board of examiners.

Delaware

Bill Enacted.—S. 248, was approved June 5, 1951. It amends the **Workmen's Compensation Act** by providing that if an employer shall, upon application made to him, refuse to furnish reasonable surgical, medical, and hospital services, medicines, and supplies, the employee may procure the same and shall receive from the employer the reasonable cost thereof.

Florida

Bills Enacted.—H. 3, became law without approval June 11, 1951. It provides regulations for the employment of **county medical examiners** and sets forth the duties of such medical examiners and the circumstances under which autopsies may be permitted. H. 8, became law without approval June 11, 1951. It provides regulations for the issuing of licenses to practice **physical therapy** by the State Board of Medical Examiners. Physical therapy is defined as the treatment of disability injury and disease by non-medical means comprising the use of massage, therapeutic exercises, and the physical, chemical, and other properties of heat, light, water, and electricity (except roentgen rays, radium, and electrosurgery). H. 193, became law without approval, June 11, 1951. It provides amendments to the **Chiropractic Act** relating to grounds for revocation of a license. Among other grounds set forth in the new law which would justify the revocation of a chiropractic license is that the licentiate permits persons not licensed to practice chiropractic in the state to set up in his office what is commonly called and termed "Traveling Clinics" and permits these unlicensed persons to practice chiropractic under color of the licentiate's certificate or to counsel or advise persons concerning the cure or treatment of any disease or body ailment. H. 194, became law without approval, June 11, 1951. It provides that no person shall operate a **chiropractic hospital** without first obtaining a license from the Florida State Board of Chiropractic Examiners, permitting him so to do. H. 799, was approved June 9, 1951. It directs the tuberculosis board to provide *adequate facilities for the* ***compulsory isolation*** *and treatment of persons* afflicted with tuberculosis. H. 1047, became law without approval, June 11, 1951. It provides that in any hospital or hospitals supported in whole or part by taxes collected in Bay County, Florida, and operated in that county, all citizens and tax payers of the county shall have the right to be admitted to such hospital or hospitals, and in the management of such hospital or hospitals **no discrimination shall be made against any physician or surgeon,** provided such physician or surgeon has been admitted to the general practice of medicine or surgery under the laws of the state, and all such physicians or surgeons shall have equal privileges in treating patients in said hospital or hospitals. The law further provides that the Board of Trustees shall organize a staff of physicians and surgeons composed of every practicing physician and surgeon in the county, and such physicians and surgeons shall hold their position on said staff as long as they comply with the rules and regulations laid down by the Board of Trustees. H. 1332, became law without approval, June 11, 1951. It authorizes certain judges and county solicitors throughout the state to secure the **services of a physician in connection with the investigation of crime** or under circumstances where such services are deemed necessary for the investigation of crime, and it fixes the fee to be paid to such physician for the services which may be rendered. H. 1385, became law without approval, June 11, 1951. It authorizes the Board of County Commissioners of Saint Lucie County to enter into contracts which would provide for its employees and the *members of their family* **medical, surgical, hospital and similar costs** resulting from illness or injury to such persons. H. 1550, became law without approval, June 11, 1951. It authorizes the board of county commissioners of certain size counties throughout the state to provide and secure insurance for its employees and the *members of their family which would provide funds to defray* **medical, surgical, hospital and similar costs** resulting from the illness of, or injury to, such persons. H. 1578, became law without approval, June 11, 1951. It authorizes the Board of County Commissioners of Broward County to appoint and employ a **County Medical Examiner** who shall be a licensed practicing physician or surgeon in the state. The law sets forth the powers and duties of such County Medical Examiner relating to autopsies and investigation of death. S. 385, was approved June 7, 1951. It provides regulations whereby persons found to have **active tuberculosis** may, under certain circumstances, be *committed to a state hospital* for treatment. S. 672, became law without approval, June 11, 1951. It provides that any condition or *impairment of health of municipal firemen* caused by **tuberculosis, hypertension or heart disease,** shall be presumed to have been suffered in line of duty unless the contrary is shown by competent evidence, provided that such firemen shall have successfully passed a physical examination on entering into such service which failed to reveal any evidence of such condition. S. 876, became law without approval, June 11, 1951. It authorizes the City Council of Miami to establish a **health plan** for officers and employees of the city and their families. S. 946, became law without approval, June 11, 1951. It authorizes the Board of County Commissioners of Alachua County, to provide a plan for **group insurance, dismemberment, accidental death, hospitalization, surgery** and **medical expense insurance** for employees and members of their family. S. 1053, became law without approval, June 11, 1951. It provides circumstances whereby **hospitals may obtain a lien** for all reasonable charges for hospital care, treatment and maintenance of ill or injured persons upon any and all causes of action accruing to such persons or their legal representatives.

Illinois

Bill Introduced.—S. 718, proposes to authorize the use of the **injunctive process** to prohibit the unlicensed practice of any profession or occupation in the state which requires a license from a state board.

Massachusetts

Bills Introduced.—H. 2554, proposes to require the committee on education to sit during the recess of the legislature to make studies relative to the establishment of a **medical school** by the University of Massachusetts. H. 2568, proposes to authorize the board of registration in medicine to examine applicants for licenses to practice **physical therapy** and to grant licenses therefor. Physical therapy is defined as the treatment of any bodily or mental condition of any person by the use of the physical, chemical and other properties of heat, light, water, electricity, massage, and active and passive exercise. The use of roentgen rays and radium for diagnostic and therapeutic purposes and the use of electricity for surgical purposes, including cauterization, would not be authorized.

Michigan

Bills Enacted.—H. 214, has become Public Act No. 175 of the Acts of 1951. It amends the narcotic law by fixing penalties for the **sale of narcotics to minors.** H. 368 has become Public Act No. 166 of the Acts of 1951. It provides an appropriation for the construction of a southwestern Michigan **tuberculosis sanatorium** somewhere in or near the city of Kalamazoo.

Pennsylvania

Bills Introduced.—H. 1259, proposes the enactment of a **uniform narcotic drug act.** H. 1314, proposes an appropriation for the purpose of reimbursing hospitals for the cost of **training student nurses** in approved schools of nursing. H. 1376, proposes to increase the size of the **Advisory Health Board** from seven (7) to ten (10) and to provide that five (5) of the members of such board should be doctors of medicine. H. 1413, proposes to make it a felony to furnish or give **narcotic drugs to a minor.** H. 1428, proposes amendments to the pharmacy act among which is a **new definition of the term "prescription"** which would mean an order for drugs or medicines or combinations or mixtures thereof written or signed by a duly licensed physician, dentist or veterinarian or other medical practitioner licensed to write prescriptions intended for the treatment or prevention of disease in man or animals.

Bills Enacted.—H. 368 was approved May 22, 1951. It is a law providing for the licensing of and regulating of **professional nurses.** H. 60, was approved May 24, 1951. It provides that in any proceeding to establish paternity the court on motion of amendment shall order the mother, her child and the defendant to submit to one or more **blood-grouping tests** by a duly qualified physician to determine whether or not the defendant can be excluded as being the father of the child and the results of such tests may be received in evidence in cases where definite exclusion of the defendant is established.

South Carolina

Bill Enacted.—H. 1039 was adopted January 17, 1951. It provides for the creation of a committee to investigate and make a study and research of the South Carolina **unemployment compensation law** with particular attention to the insurance rates in South Carolina and other jurisdictions.

Vermont

Bill Introduced.—H. 386, proposes the appointment of a special commission to investigate the conditions existing at the **Vermont state hospital.**

Bills Enacted.—H. 229 was approved April 13, 1951. It requires superintendents of schools to cause a qualified person to **test the hearing** of all pupils under his supervision in grades one, two, three, five, seven, and nine. The prior law permitted such examination to be made by teachers. H. 261, was approved May 18, 1951. It provides for the establishment of an **alcoholic rehabilitation commission** to assist in the control of the effects of alcoholic beverage consumption by the establishment of a state program for medical and other scientific care and treatment and rehabilitation of alcoholics. H. 270, was approved April 10, 1951. It is an **occupational disease law.**

Prepared by the Bureau of Legal Medicine and Legislation.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE ANNUAL SESSION IN ATLANTIC CITY, N. J., JUNE 11-15, 1951

The actions of the House of Delegates at the Atlantic City Session are herewith abstracted so that the readers may have this information in digest form. The official proceedings will be made available, as in the past, in a booklet, which will be sent to all members of the House of Delegates and officers of the American Medical Association by the Secretary. This booklet will not be available for several weeks.—Ed.

Invocation

Rev. Harvey Bennett, Pastor of First Presbyterian Church of Atlantic City, delivered the following invocation:

Almighty and Eternal God, Infinite Architect of the Universe, by whose power the worlds were formed, by whose laws the planets run their courses, by whose inspiration scholars have searched for truth, prophets preached and poets penned their poems of life, to whom all hearts are open, all desires known, and from whom no secrets are hid, whose excellency is more than we can know, yet Thou art all that we adore. From the confused voices of our life we turn to Thy silent presence. From Thy darkened skies we venture forth into Thy pure and infinite light. In Thy light, may we see light. Through Thine infinite wisdom may we have that wisdom which shall discern truth from falsehood, right from wrong, justice from injustice.

O God, our heavenly Father, we commend to Thy divine providence this noble company of physicians, delegates to the American Medical Association, as they have assembled themselves in our city by the sea for their hundredth annual session. We are conscious that Thou hast blessed their consecrated efforts in the past as they have diligently and earnestly labored to alleviate pain and suffering by the touch of their skillful hands, administered in love to the afflicted bodies of mankind. As they follow in the footsteps of the Divine Physician of Life, and as they diligently search, may they find new methods of aiding those who suffer. Give to them a new sense of their responsibility and added strength for the tasks that lie before them.

And O God, we ask these blessings upon Thy servants who go about night and day alleviating suffering, in the name of Jesus Christ who while on the earth went about healing the broken bodies of men, giving hope to the hopeless, and life to the lifeless. Amen.

Adoption of Proceedings of Cleveland Clinical Session

Dr. George F. Lull, Secretary, presented the Proceedings of the Cleveland Clinical Session as printed and distributed to the members of the House of Delegates, which on motion of Dr. Val H. Fuchs, Louisiana, seconded by Dr. Charles H. Phifer, Illinois, and carried, were adopted as published.

Roll Call

The Secretary, Dr. George F. Lull, called the roll and announced that more than a quorum had responded.

Address of Speaker

The Vice Speaker, Dr. James R. Reuling, took the chair while Dr. F. F. Borzell, Speaker, presented the following address, which was referred to the Reference Committee on Reports of Officers, with the exception of the portion dealing with the creation of a new reference committee which was referred to the Reference Committee on Amendments to the Constitution and By-laws.

Members of the House of Delegates:

We are opening the One Hundredth Annual Session of the House of Delegates of the American Medical Association. My first task is to pay tribute to the passing of Dr. Roy Fouts who has gone to his reward since we last convened. Dr. Fouts was a member of this House for many years, the last few of which he served as your Speaker. We mourn his loss as a man, as a statesman, as a staunch supporter of and fighter for those high principles on which our profession is based. He rightfully belongs in that great gallery of medical men whose services to organized medicine have laid firm foundations on which we can build with assurance that the structure will withstand the bitter winds of adversity and the strife of a troubled world. We can, with sincerity, say that he fought a good fight and he kept the faith.

I must also inject another note of sadness by the announcement of the death of one who has served this House and the American Medical Association for many years. Miss Jewel Whelan passed away just a few weeks ago. She was to retire after this Session after many years of faithful and devoted service to the American Medical Association.

A centennial anniversary should be an occasion for reminiscences and review of the accomplishments of the organization but this is neither the time nor the place for such pleasant pastimes.

The passing years have not eased our tasks or reduced our responsibilities. On the contrary, because our predecessors have built so well, we find ourselves in the forefront of a struggle for the preservation of the very fundamentals of those principles which make life worth living. There have been times when clouds were dark and it looked as though our structure would crumble, but I say to you in all sincerity that the American Medical Association was never stronger than it is today.

A review of the activities of this body through the years reveals a steadfast adherence to sound principles, high ideals, and an unswerving code of ethical conduct of which we need not be ashamed. Today the world looks to this House of Delegates as the true voice of American medicine. Throughout the years every action taken by this House was measured in terms of what would be best for those we serve. We have not hesitated to modify our positions if we found in so doing we were improving the quality of medical service to the people.

The officers we have elected to direct the affairs of the Association voice only the policies this House adopts. We, in turn, are the elected representatives of almost the entire profession of America. Any inference that a handful of self-interested individuals tells us what to think is so contrary to the history of the body as to constitute a libelous slander on the integrity and intelligence of the vast majority of the physicians of the country.

You have each just within the last few weeks received a communication which implied that you are naive children who have been led astray. I refer to the letter from the Committee for the Nation's Health under date of May 22:

"In order that the medical profession will not be justified in feeling that President Henderson had spoken accurately because no denial has been made in the medical press by the Committee for the Nation's Health, the Committee sends a copy of its letter to President Henderson with the hope that the officers of the American Medical Association and of the state societies will be glad to enlighten the medical profession even if Dr. Henderson does not wish to do so."

Dr. Henderson certainly needs no defense for his courageous and untiring leadership these many years, but is there not in this letter a semblance of invidious reflection on the integrity and intelligence of the House? I apologize for having possibly digressed from the established policy that the Speaker should not make a speech but in justification I can only say that as your Speaker and as a member of this House for sixteen years I most emphatically defend the House against any implied reflection on its intelligence.

There are two events which mark the opening of this One Hundredth Session which call for special attention.

The first is the initial attendance, as special delegates, the first representatives of the newborn Student American Medical Association. May I, at this time, introduce to the House:

Warren R. Mullen, of Jackson, Mich., a student at the University of Michigan Medical College and President of the Student American Medical Association.

Harry W. Sandberg, of Moline, Ill., a student of Illinois College of Medicine, Chicago. He is Vice President of the Student American Medical Association.

I had hoped this morning to introduce the new Surgeon General of the Army, Dr. George Armstrong, who expected to act as delegate from the United States Army but who because of illness was compelled to ask the Deputy Surgeon General Paul Streit to serve.

It has been necessary for a few years past to request the House for authority to appoint a special Reference Committee on Emergency Medical Service. This must be done again at this Session. It seems, however, that the emergency has become a permanent condition. This House has authorized a new section on Military Medicine which is receiving enthusiastic support. In order, then to provide a reference committee that can consider the many problems involving military medical affairs and to permit the advance publication of the personnel of this committee with other standing reference committees, the Speaker would recommend that the House approve an amendment to establish a new reference committee to be known as The Reference Committee on Medical Military Affairs and Civil Defense.

REFERENCE COMMITTEES OF HOUSE OF DELEGATES

The reference committees and appointments for this Session are as printed in the Handbook including changes, as follows:

SECTIONS AND SECTION WORK:

Willard A. Wright, *Chairman*, North Dakota
Percival Bailey, Section on Nervous and Mental Diseases
Harvey B. Matthews, Section on Obstetrics and Gynecology
Norman S. Moore, New York
Arthur A. Brindley, Ohio

RULES AND ORDER OF BUSINESS:

Walter E. Vest, *Chairman*, West Virginia
Dexter H. Witte, Wisconsin
John M. Porter, Kansas
William A. Hyland, Michigan
James P. Wall, Mississippi

REPORTS OF BOARD OF TRUSTEES AND SECRETARY:

Edgar V. Allen, *Chairman*, Section on Experimental Medicine and Therapeutics
Val H. Fuchs, Louisiana
Jacob W. Bird, Maryland
Charles G. Hayden, Massachusetts
Robert E. Schlueter, Missouri

MEDICAL EDUCATION AND HOSPITALS:

William Bates, *Chairman*, Pennsylvania
James S. Stevenson, Oklahoma
Joseph F. Londrigan, New Jersey
Henry S. Ruth, Section on Anesthesiology
Harlan A. English, Illinois

LEGISLATION AND PUBLIC RELATIONS:

Leo G. Christian, *Chairman*, Michigan
Hugh H. Hussey Jr., District of Columbia
J. Paul Jones, Alabama
Denver M. Vickers, New York
William W. Skipp, Ohio

HYGIENE AND PUBLIC HEALTH:

Louis M. Orr II, *Chairman*, Florida
W. Palmer Dearing, United States Public Health Service
Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health
Charles F. Strosnider, North Carolina
Herbert H. Bauckus, New York

AMENDMENTS TO CONSTITUTION AND BY-LAWS:

Robertson Ward, *Chairman*, California
Jesse D. Hamer, Arizona
Everett P. Coleman, Illinois
George Braunlich, Iowa
J. B. Lukins, Kentucky

REPORTS OF OFFICERS:

Britton E. Pickett Sr., *Chairman*, Texas
George M. Fister, Utah
John M. Emmett, Virginia
Harold F. R. Brown, New York
William F. Costello, New Jersey

CREDENTIALS:

H. Russell Brown, *Chairman*, South Dakota
Karl S. J. Hohlen, Nebraska
Charles L. Farrell, Rhode Island
Charles T. Stone Sr., Section on Internal Medicine
Everett C. Fox, Section on Dermatology and Syphilology

INDUSTRIAL HEALTH:

Earle M. Chapman, *Chairman*, Massachusetts
Ralph A. Johnson, Michigan
Bertie O. Edwards, North Carolina
Carlton E. Wertz, New York
James Z. Appel, Pennsylvania

EXECUTIVE SESSION:

Homer G. Hamer, *Chairman*, Indiana
Howard K. Petry, Pennsylvania
Donald Cass, California
Willis I. Lewis, Illinois
Charles J. Kickham, Massachusetts

INSURANCE AND MEDICAL SERVICE:

William R. Brooksher, *Chairman*, Arkansas
Maurice J. Dattelbaum, New York
John W. Green, California
William H. Halley, Colorado
Benjamin H. Minchew, Georgia

MISCELLANEOUS BUSINESS:

Andrew A. Eggston, *Chairman*, New York
Thomas J. Danaher, Connecticut
Alfred S. Hartwell, Hawaii
Hoyt B. Woolley, Idaho
Clifford C. Sherburne, Ohio

TELLERS:

George S. Klump, *Chairman*, Pennsylvania
Eugene F. Hoffman, California
Robert H. Hayes, Illinois
Deering G. Smith, New Hampshire
Carl H. Gellenthien, New Mexico

SERGEANTS AT ARMS:

Hollis E. Johnson, *Chief*, Section on Diseases of the Chest
John K. Glen, Texas
Charles M. Hamilton, Tennessee

The Speaker respectfully requests the authorization of a Special Reference Committee on Emergency Medical Service as follows:

J. Arnold Bargen, *Chairman*, Minnesota
Frank H. Krusen, Section on Physical Medicine and Rehabilitation
L. Howard Schriver, Ohio
Elmer Hess, Pennsylvania
Raymond L. Zech, Washington
Paul Streit, U. S. Army
Clarence J. Brown, U. S. Navy
Dan C. Ogle, U. S. Air Force
George Lyon, Veterans Administration

IN MEMORIAM

The Speaker read the list of names of former members of the House of Delegates and Officers of the Association who had passed away during the past year, after which the members of the House rose in respect to the departed members and officers:

Report of Reference Committee on Reports of Officers

Dr. B. E. Pickett Sr., Chairman, presented the following report which was adopted section by section and as a whole:

The Speaker's tribute to the memory of Dr. Roy Fouts, a former Speaker of this body, well expresses the sentiments of this House of Delegates.

Your reference committee commends the forceful remarks of the Speaker, especially in his discussion of the steadfastness, high ideals and ethical conduct of the American Medical Association through the years. It is the sense of this committee that we cannot better express that which we would convey to you than by quoting a paragraph from the Speaker's remarks:

"A review of the activities of this body through the years reveals a steadfast adherence to sound principles, high ideals, and an unswerving code of ethical conduct of which we need not be ashamed. Today the world looks to this House of Delegates as the true voice of American medicine. Throughout the years every action taken by this House was measured in terms of what would be best for those we serve. We have not hesitated to modify our positions if we found in so doing we were improving the quality of medical service to the people."

The Speaker's treatment of the situation involving a letter from the Committee for the Nation's Health properly interprets the position of the American Medical Association on this question, and your committee agrees in its entirety with the support of President Henderson in this matter.

Report of Reference Committee on Amendments to Constitution and By-Laws

The Reference Committee on Amendments to Constitution and By-Laws presented the following report which was adopted and the By-Laws so amended:

The Speaker, in his address to the House at the opening meeting, suggested the establishment of a Reference Committee on Military Affairs. This was to eliminate the necessity for the appointment of a special reference committee at each session of the House to handle these subjects. This had been anticipated by the Interim Committee on Constitution and By-Laws, and in Dr. McCarthy's report he had moved for a change in the By-Laws, as follows: Add paragraph (14) "Medical Military Affairs, to which will be referred all matters relating to military affairs and civilian defense." Division 3, Chapter X, Section 5 (D).

Resolution on Death of Dr. Roy W. Fouts

Dr. James P. Wall, Mississippi, presented the following resolutions, which were adopted on motion of Dr. Wall, seconded by several delegates and carried by a standing vote:

Life, with its ever changing cycle, brings experiences of varied kinds—some fraught with gladness, others laden with sadness. Man has a time to come and a time to go, yet his tenure is commensurate not with years spent, but rather in deeds wrought. In the course of human events the passing from God's footstool is to be expected, and though mindful of the immutability of such a law, mere mortals are never prepared for the inevitability of this denouement. It is true that posthumous glory soon sinks into forgetfulness, it is equally true that a good man lives long after he has dropped into the tongueless silence of a dreamless sleep.

An estimate of one's character is very apt to be biased by personal relation and association, and a true evaluation is merged into the maze of circumstance and lost in the exigencies of time. Nevertheless, there has come to this House of Delegates the grim realization that it suffered a great sorrow when death came, as it must come to all, to Dr. Roy W. Fouts on March 27, 1951.

Dr. Fouts was all the term "gentleman" connotes. Gentle, without fear; meek, without repining; modest, without prudery; gifted, without pedantry and friendly, without effusion. No one ever had the temerity to question his motives, impugn his integrity, asperse his character or doubt his courage. Unswayed by popular clamor he kept the even tenor of his way, possessed of a fine intellect, a wonderful calmness, a rare poise, a kindly disposition, an unusual sense of humor, a clear understanding of his vocation and a due appreciation of the weightier matters of life.

As a member, Vice Speaker and Speaker of the House of Delegates of the American Medical Association, he was at all times considerate of the rights of others, fair in his rulings and impartial in the conduct of these offices. As Vice President of the American Medical Association, being a firm believer in the righteousness of its cause, he worked in and out of season to promote those standards that have made American medicine the standard of the world.

Though not unmindful that expressions of condolence often fall far short of their intended meaning and that many times words of sympathy are mere emptiness, this House, knowing Dr. Fouts as it did, knows it has suffered a great loss, and it is seeming and fitting at this time that it should take cognizance of the passing of our confrere; therefore be it

Resolved, By the House of Delegates of the American Medical Association in Annual Session in Atlantic City, New Jersey, June 11, 1951, that in the slipping away of Dr. Roy W. Fouts this body has lost a stalwart defender of its most precious tenets; organized medicine, a warrior worthy of his steel; the community an upright citizen, and the Healing Art, an exponent of whom it may truly be said: "He was a workman that needeth not be ashamed"; and be it further

Resolved, That a copy of these resolutions be forwarded to the family of our deceased comrade and friend.

An official photograph of the House of Delegates was taken.

Distinguished Service Award to Dr. Allen O. Whipple

Dr. Louis H. Bauer, Chairman, Board of Trustees presented the report of the Committee on Distinguished Service Award of the American Medical Association which submitted five names to the Board of Trustees, from which the Board selected the following three in alphabetical order: Maj. Gen. Harry G. Armstrong, Surgeon General of the U. S. Air Force; Dr. Torald Sollmann, Cleveland; and Dr. Allen O. Whipple, New York City. The result of the first ballot for recipient for the Distinguished Service Award was as follows:

Dr. Armstrong, 61; Dr. Sollmann, 50 and Dr. Whipple, 71.

The Speaker announced that since there was no majority, the one receiving the lowest number of ballots would be eliminated and the House would proceed to vote on the other two. Ballots were again distributed for a vote for either Dr. Armstrong or Dr. Whipple.

Dr. George S. Klump, Chairman of the Tellers, reported that Dr. Armstrong had received 80 votes and Dr. Whipple 98, and the Speaker declared Dr. Allen O. Whipple, New York, the recipient of the Distinguished Service Award for 1951. (See THE JOURNAL, June 23, 1951, page 735.)

Contribution to American Medical Education Fund by American College of Radiology

Dr. Warren W. Furey, Illinois, on behalf of the American College of Radiology, presented to the House a check of that organization for $2,000.00 in contribution to the American Medical Education Fund, which was received by the Speaker with thanks to the College.

Address of Past President James E. Paullin

Dr. James E. Paullin, Past President, addressed the House as follows:

Mr. Speaker, Members of the House of Delegates: A little over a year ago this House passed a resolution extending to Mrs. Paullin and me its sympathy and prayers for a speedy recovery from an automobile accident which happened to us. This resolution was delayed in reaching me and I did not have an opportunity to express our deep and abiding pleasure at receiving thoughts from such a noble organization. While my thanks and those of my good wife are delayed in reaching you, I wish to present myself today in person in answer to your prayers, recovered wholly, and I am delighted to be back with you. Thank you.

Report of Reference Committee on Rules and Order of Business

Dr. Walter E. Vest, Chairman, presented the following report and moved its adoption. The motion was seconded and carried, after which the Speaker announced that the chairmen of the reference committees would meet with the Vice Speaker immediately on adjournment of the meeting:

Mr. Speaker and Gentlemen of the House: Your Committee on Rules and Order of Business offers the following preliminary report: That we recess at 1:00 p. m. today and reconvene at 2:30 p. m.; that all committees (and that means all, every committee; and we want every member of every committee there) meet for hearings promptly at 9:30 a. m. Tuesday, and that the House will recess this afternoon until 9:00 a. m. Wednesday.

Your committee sees now no reason for an executive session. If the occasion should arise, we will consider that of course; but at present we see no reason for it.

Address of the President, Dr. Elmer L. Henderson

Dr. Elmer L. Henderson, President, presented the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker, Members of the House of Delegates:

For the past two and one-half years we of the medical profession have devoted a great deal of time and energy to our battle against the advocates of socialized medicine. Despite the intensity of that battle, the American Medical Association not only has continued, but has accelerated, its many positive activities designed to advance the health of the nation. With the socialistic threat now dispelled, at least temporarily, I believe that this is a good time to remind both doctors and the public of the basic, long-range objectives of this organization. Stated briefly, those objectives are to promote the national health through scientific activities, to foster and maintain high standards of medical practice, and to solve health problems in a manner most conducive to the public welfare.

The American Medical Association has a wide range of interests and programs based on those positive objectives. Today, therefore, in my last report to you as President of the American Medical Association, I should like to touch on a number of developments or activities aimed at our long-range goals.

1. We have taken recent steps to make possible a concerted, nationwide effort to demonstrate how private initiative can meet the financial problems of American medical schools. On last May 16 the American Medical Education Foundation was merged with the National Fund for Medical Education, of which Mr. Herbert Hoover is honorary chairman.

The American Medical Education Foundation will continue to solicit funds from physicians, medical organizations and others in the field of medicine. The National Fund for Medical Education will concentrate its money-raising efforts on lay groups, business, industry and all other potential private donors outside the medical profession. All funds collected will be channelled to the National Fund for Medical Education, which will serve also as the distributing agency. It is anticipated that the first distribution of funds to medical schools will be made on or about July 1 of this year.

I urge all American doctors to give maximum support to the continuing drive for private aid to medical education. This new fund-raising consolidation marks only the beginning of an accelerated, large-scale offensive to show that American methods can provide the nation's medical schools with both solvency and freedom.

2. We are cooperating actively with other professional groups to meet the problems of hospital standardization. After nine months of careful study and planning with the American College of Surgeons, the American College of Physicians and the American Hospital Association, a plan has been formulated relative to the accreditation of hospitals. This program, it should be understood, has no relationship to the intern and residency training program. The plan is covered in detail in the Board of Trustees' report. The committee which represented the American Medical Association believes that it is an excellent solution of the problem.

3. We are placing particular emphasis on efforts to promote the maximum growth and development of voluntary health insurance. Our objective is low-cost, comprehensive protection, available on a sound medical and financial basis to every American who needs it or wants it. To this end, our Council on Medical Service and other interested American Medical Association departments are cooperating with medical societies, hospitals, insurance companies, labor unions, business and industrial concerns, farm and fraternal organizations, and all other sound agencies in the field. As a result of the efforts by all concerned, in the direction of both increased enrolments and improved coverage, it is estimated that close to 80 million Americans will be protected by some form of voluntary health insurance at the end of this year.

4. We are advocating the establishment and effective use of grievance committees to iron out misunderstandings between physicians and patients, and we are giving active assistance to state and county medical societies to further that objective. Such programs now are in operation in at least three-fourths of the states and in more than 400 counties.

5. We are encouraging and aiding the establishment of night and emergency call systems, to assure 24-hour medical service in local communities. The number of such plans set up by county medical societies increased from 60 in 1948 to 329 in January of this year, and we expect to stimulate a sharp increase in that rate of growth during the next year or two.

6. We are urging physicians and medical societies to play a leading role in the development and operation of community health councils, to solve local health problems and improve local health facilities. As a result, there now are some 1,200 community health councils or committees and 30 state health councils.

7. We are working constantly to assure an adequate supply of properly trained physicians, and there is no better evidence of that work than the fact that the United States has more doctors in proportion to population than any other country except Israel. Furthermore, we also are working constantly to improve the distribution of physicians, and we are urging every state medical association to adopt an active program for placing doctors in communities which need them. In this connection, incidentally, the number of doctors seeking location now exceeds the number of communities looking for doctors.

8. We are encouraging and promoting increased interest in general practice and greater emphasis on the training of good family doctors in the medical schools and in the scientific meetings and activities of the American Medical Association and other professional organizations. Recent surveys by the Council on Medical Education and Hospitals show that general practice is attracting an increasing percentage of medical students and young physicians.

Because of this definite trend, and to help stimulate it further, I have a suggestion regarding the annual award given to the general practitioner of the year. In the past, as you know, all of the recipients of the annual medal have been fine, outstanding men beyond middle age. But there also are many excellent young doctors in general practice, and their number is increasing. Therefore, I recommend that we establish two annual awards for outstanding general practitioners, one to a member over 50 years of age, and the other to a member under 50.

9. We are continuing and expanding the many scientific activities which make the American Medical Association the focal point of American health progress in this era of dramatic, fast-moving advance. Playing an important part in this work, both to inform the medical profession and protect the public, are the Council on Pharmacy and Chemistry, the Council on Physical Medicine and Rehabilitation, the Council on Foods and Nutrition, the Bureau of Investigation and a wide variety of additional bureaus and committees.

10. We are keeping doctors up to date on the latest medical advances by means of the annual and clinical sessions of the American Medical Association, THE JOURNAL and other scientific publications of the association, and an extensive library and informational service. At the same time we are keeping the public informed through the lay publications and many other activities of the Bureau of Health Education. Speaking of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, you will be interested to hear that its weekly circulation has increased from 137,000 to 168,000 since establishment of the annual dues payment including a JOURNAL subscription.

At this point I would like to commend our Editor, Dr. Austin Smith, and his staff for the outstanding job they have done in the improvement not only of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION but also of the special journals.

11. We are continually working with both employers and employees to reduce health hazards in industry, and our Council on Industrial Health sponsors an annual congress to spur progress in that field.

12. We are doing a great deal of special work through our Committee on Rural Health, which also holds an annual conference devoted to the solution of health and medical care problems in rural areas.

13. We are working to bring about a closer relation between medical affairs and federal activities by means of our Washington office, the Committee on Legislation and the Bureau of Legal Medicine and Legislation.

14. We are cooperating with the federal government, the armed forces and all other interested agencies—through our Council on National Emergency Medical Service—to assure a proper supply and distribution of doctors to serve the interests of national defense and security.

15. We are taking an active part in the international activities of the World Medical Association, which I have the honor of heading, and American doctors are a major factor in the financial support of that worthy instrument for aiding world cooperation.

Despite the fact that I have touched on 15 different areas of activity, I have only scratched the surface of the American Medical Association's many and varied projects in the scientific, professional, social, and economic phases of medicine. It is our determination that these positive activities will continue to expand, in pace with the tremendous progress of this free nation, and for the benefit of all the American people. That is why we have been fighting for two and one-half years to save American medicine from the deadly hand of bureaucratic control. And in that connection, before I close, I have an announcement to make concerning the National Education Campaign.

Your Campaign Coordinating Committee and Board of Trustees, acting on the recommendation of Clem Whitaker and Leone Baxter, the campaign directors, have decided to terminate the National Education Campaign at the end of this year. We agree that the great campaign success of the past two and one-half years, plus the additional progress expected during the remainder of 1951, in cementing our now strong position with the public, will make it unnecessary to continue an intensive program in 1952.

As we approach the end of the National Education Campaign, however, we should broaden the permanent public relations program carried on by the regular staff of the American Medical Association. This should be done, not only to hold the ground already gained, and to ward off any new attacks which might be made, but also to continue the positive educational work which is so necessary for the long-range future of American medicine.

As of now, we have defeated the efforts to socialize medicine through the enactment of compulsory health insurance, and we have moved a long way toward the ultimate goal of proving that voluntary methods can solve American medical care problems.

The progress in our National Education Campaign and in related activities represents a tremendous amount of hard work by your American Medical Association officers and staff, by the Coordinating Committee and Board of Trustees, by the officers and lay staffs of the state and county medical societies and by the women's auxiliaries. Thousands of individual doctors throughout the country have given time and effort in almost superhuman proportions to help make medicine's campaign successful.

As Chairman of the Coordinating Committee and the Board of Trustees, and then for the past year as President, I have appreciated deeply your cooperation, and that of all American doctors, in the great mutual tasks which we have had to perform. In particular, there are no words to express my personal appreciation for the brand of close cooperation in many difficult times exhibited by the hard working and dedicated members of your Campaign Coordinating Committee and the Board of Trustees. They deserve this Association's sincere gratitude for a difficult job well done.

As a final personal word, in my last formal address as your President, I want to say that it has been a great honor and a stimulating experience to have been a leader in the American Medical Association during the recent past. And if I may steal a bit from the famous address by General MacArthur, I should like to say this, as an old soldier in the ranks of medicine: I do not intend to die very soon, and I do not intend to fade away; if the fight flares up again, I shall be glad to be a private in the rear ranks.

NATIONAL EDUCATION CAMPAIGN

This is not part of my formal address, but I should like to take this opportunity to make one more statement regarding the National Education Campaign. I want to say that no one has worked as hard, as long, and with such high devotion to the cause of American medicine, as have Clem Whitaker and Leone Baxter, the active campaign directors. Since January, 1949, they have lived and breathed medicine's fight for freedom 24 hours a day, and seven days a week. They have given us not only inspired direction, ability, and experience in public relations and not only tremendous physical and mental effort but also a heart-and-soul dedication to our battle and an unshakable confidence in our ability to win.

It has truly been two and a half years of "blood, sweat and tears" for Whitaker and Baxter, but they have never faltered, they have never given up—they have brought us through with banners flying, and they have paved the way for still more significant progress during the remainder of the campaign. As Chairman of the Coordinating Committee, I have been in almost daily contact with them excepting when I was beyond the boundaries of the United States and I personally know of the many problems and difficulties with which they have had to contend and of their unselfish devotion to our cause. At this point I wish to express the deep appreciation of the medical profession and my personal appreciation to Clem Whitaker and Leone Baxter for their outstanding work in behalf of freedom in medical practice.

On motion of Dr. Walter E. Vest, West Virginia, seconded by several delegates and carried, the members of the House arose and applauded the President's remarks regarding Whitaker and Baxter.

Presentation of President-Elect John W. Cline and Vice President R. B. Robins

The speaker presented to the House the President-Elect, Dr. John W. Cline, and the Vice President, Dr. R. B. Robins.

Report of Board of Trustees

Dr. Louis H. Bauer, Chairman, presented the following report, which was referred to reference committees as follows:

To the Reference Committee on Reports of Board of Trustees and Secretary: Exemptions from Membership Dues; Twelve Point Program; Public Relations Department Expansion; Student American Medical Association; Appointment to Membership on Council on Scientific Assembly; Resolution on Absentee Ballot Adopted at Cleveland Session, and Treasurer's and Auditor's Report.

To the Reference Committee on Medical Education and Hospitals: Hospital Standardization and Aid to Medical Schools for Construction Only.

To the Reference Committee on Insurance and Medical Service: Inter-Association Committee on Health:

To the Members of the House of Delegates of the American Medical Association:

The following report of the Board of Trustees is respectfully submitted:

Financial Statement

The official reports of the Treasurer and of the Association's auditors are appended as a part of this report.

1950 was the first year in which members of the American Medical Association were called on to pay membership dues, and on Dec. 31, 1950 $2,655,785.00 in dues had been collected. An additional amount of $183,617.50 was collected between Dec. 31, 1950 and March 31, 1951.

Of the dues collected in 1950, $2,346,955.58 was allocated to the National Education Campaign. This, with the unexpended balance of $676,145.45 reserved at Dec. 31, 1949 and $70,284.50 of 1949 assessments paid in 1950 covered the cost of the Education Campaign. The campaign cost $3,093,385.53, which included $500,000.00 used for the establishment of the American Medical Education Foundation. The remainder of dues collected in the amount of $308,829.42 was transferred to ordinary income of the Association. This and other 1950 income are listed below:

Membership dues for 1950, less $2,346,955.58 allocated to National Education Campaign	$ 308,829.42
Fellowship dues	70,319.00
Income from Investments	169,520.81
Miscellaneous receipts and other income	40,312.10
	$ 588,981.33
Periodical subscriptions	2,315,212.39
Periodical advertising	2,599,306.74
	$5,503,500.46

Periodical publication costs and expenses were: Salaries and wages, $1,225,427.99; paper and ink, $674,848.83; illustrations, *$79,245.45; contract printing, $127,069.71; postage and cartage,* $193,102.11; editorial, excluding wages, $132,446.75; advertising sales and service, excluding wages, $95,946.92; circulation, excluding wages, $364,429.63; other costs including allocation of building and plant maintenance, depreciation, taxes and employee welfare, $282,301.47; *total,* $3,174,818.86.

The publication of the Eighteenth Edition of the American Medical Directory in 1950, covering a long compilation period, resulted in a loss of $43,161.86.

The Quarterly Cumulative Index Medicus was published at a *loss of $71,877.65 after provision for the fulfillment of* orders of unpublished volumes. Books, pamphlets and authors' reprints were sold at a loss of $57,104.59.

The net cost of conducting the Annual and Clinical Sessions was $72,214.47.

These items and the operation expense of Councils, Bureaus and related activities of the Association in the amount of $1,838,381.85, employees past service annuities and retirements $135,546.80, cash discounts $36,104.66, depreciation and taxes unallocated $32,160.65, legal and sundry $14,328.62, together aggregating $5,475,700.01, are a deduction from income. The net income in excess of expenses for the year 1950 is $27,800.45.

There was an increase in periodical publication advertising income in 1950 over 1949 of $167,469.11 and an increase in subscription income of $34,702.21.

Additions to investments for building improvements amounted to $52,061.98. There was also expended $59,545.67 for machinery, printing equipment, office furniture and laboratory equipment.

During the year the Association purchased common stocks for investment at a cost of $424,071.99. A modest increase in value is not reflected in the portfolio total, since cost prices are used as the basis for the evaluation of all securities in the annual statements. The Association owned securities on Dec. 31, 1950 valued at cost in the amount of $6,240,251.61. Of this amount $1,490,103.13 is held in the American Medical Research Fund and $500,000.00 in the recently established Fund of the American Medical Education Foundation. The remainder of $4,250,148.48 represents investments of the

General Fund	$ 700,148.48
Depreciation Reserve Fund	1,375,000.00
Association Reserve Fund	350,000.00
Retirement Reserve Fund	675,000.00
Building Reserve Fund	450,000.00
Equipment Modernization Reserve Fund	700,000.00

Exemptions from Membership Dues

The Board of Trustees has established the following exemptions from the payment of American Medical Association membership dues:

(1) Members who have retired from the practice of medicine, provided they are also excused from the payment of dues, in full or in part, by their component societies and constituent associations. (This will necessitate an amendment to the By-Laws, Chapter II, Section 3, and has been brought to the attention of the Committee on Constitution and By-Laws.)

(2) Members over 70 years of age, regardless of whether or not they are in practice and regardless of local dues exemption.

(3) Members for whom the payment of dues constitutes a financial hardship and who are also excused from the payment, in full or in part, of component and constituent society dues for the same reason. In each case, notification of exemption for financial hardship should be made to the American Medical Association by the secretary of the county and state medical society.

(4) Interns and residents not more than five years after graduation from medical school, except that time spent in military service may be excluded in calculating the five year limit.

(5) Members who enter military service prior to July 1 of any year are exempted from one half of the year's dues and subsequently during service from full dues.

Hospital Standardization

In its report to the House of Delegates at the Cleveland Session the Board of Trustees stated that a joint committee of the American Medical Association, the American College of Surgeons, the American College of Physicians and the American Hospital Association had been appointed, after numerous conferences of representatives of the four organizations, to draft a basic plan for a cooperative program in the field of hospital standardization. This group, which is now called the Joint Commission on Accreditation of Hospitals, has prepared the following *report, which is referred to the House of Delegates with the* approval of the Board of Trustees:

JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

The American College of Surgeons for more than twenty-five years has administered a successful hospital standardization or accreditation program, developing standards, inspecting hospitals and approving those hospitals which met minimum standards. Because of the expanding scope and requirements of this program during the intervening years, its financing has become more and more demanding.

In the fall of 1950 the American College of Surgeons invited representatives of the American College of Physicians, American Hospital Association and American Medical Association to meet with representatives of the American College of Surgeons to discuss the establishment of a joint hospital accreditation program. *After frequent meetings over a period of six months, the* details of a plan for such a joint program were adopted unanimously by this conference committee. Representatives of each of the four organizations were designated as a subcommittee of four to prepare this statement for publication. There follows an outline on the basic pattern of the proposal for a joint hospital accreditation program as worked out by the large committee and recommended to the four organizations.

The proposal provides for the establishment of a Joint Commission on Accreditation of Hospitals. Members of the Commission will be constituent organizations, each of which will be represented by appointees of its choice. Basically the Commission will be composed of three representatives of the American College of Physicians; three representatives of the American College of Surgeons; six representatives of the American Hospital Association, and six representatives of the American Medical Association.

The exact composition of the Commission, however, will depend on the acceptance of an invitation to participate to be extended to the Canadian Medical Association. Since both Colleges and the American Hospital Association number Canadian members in their organization, it was the consensus of the conferees on the interim committee that Canadian interests in these fields would be represented by their parent organizations, but that the medical profession in Canada as a whole might desire representation similar to that proposed for the American Medical Association. If the invitation to participate is accepted by the Canadian Medical Association, *the apportionment of commissioners among* the constituent organizations will be adjusted to provide such representation.

The Joint Commission on Accreditation of Hospitals will formulate standards, determine the type and scope of inspections, allocate hospitals for inspection to the several participating organizations, maintain records and award all certificates of accreditation. It will be the sole and final authority on these matters. The Commission will employ a small staff to be directed by a physician, preferably one experienced in hospital administration.

Except in unusual or controversial cases, the staff of the Commission will make no inspections. Inspections will ordinarily be made by the field staffs of constituent organizations and may be combined with other inspections made by these organizations for other purposes, such as approval for intern and resident training.

All inspections for the purposes of hospital accreditation under this program will be made and reported in a uniform manner to be determined by the Commission, and such reports of inspection will be evaluated by the staff of the Commission and acted on by the Commission itself. There will be no interference with other types of inspections made by the constituent organizations.

The budget of the Commission will be met by the constituent organizations in the same proportion as their representation on the Commission. The initial annual budget has been estimated at approximately $70,000. Additional expenses will be borne by the constituent organizations for financing field staff work and other activities incidental to the maintenance of necessary inspection records required for the conduct of special approval programs conducted by constituent organizations.

The Regents of the American College of Physicians and the American College of Surgeons have approved the proposal for the establishment and financing of the Joint Commission on Accreditation of Hospitals. Similar consideration of the proposal will be given by the American Hospital Association at its annual meeting in September 1951.

Inter-Association Committee on Health

The Inter-Association Committee on Health, consisting of representatives of the American Dental Association, the American Hospital Association, the American Medical Association, the American Nurses' Association, the American Public Health Association and the American Public Welfare Association, has approved three statements which are herewith submitted to the House of Delegates for its consideration:

STATEMENT ON MATERNAL AND CHILD HEALTH

The coming of a baby, its nurturing and protection during the early formative years, is the center of any program of health and medical care. From this natural, normal functioning of the body and the mind stems the prevention of disease and the treatment of disease among people of all ages.

In the past few years of public debate about health and medical care programs, in which many groups have presented their opinions, a number of points of agreement about the care of mothers and children have come to light. Among them are the following:

I. Every mother and child should have equal opportunity for the best care known to medical and related sciences for the promotion of health, the prevention of disease and the treatment of disease.

II. Modern diagnostic and treatment facilities should be available to every physician who cares for mothers and children.

III. Many communities, because of geographic location or low income, do not have adequate facilities for the care of mothers and children or for the continuing education of doctors and other professional workers. It will be necessary to create an awareness of this need for adequate facilities and competent professional workers among the people in local communities and states. From this awareness will spring a desire among citizens and professional workers alike to weave a regional network of services and facilities through which adequate maternal and child care can be provided. Within this regional organization, specialized skills can then be brought to the local community as needed; resources for diagnosis, treatment and education of patients can be organized within the communities, or patients may be sent to regional centers for these specified skills. This regional organization would require the integration of local community hospitals, clinics, health centers and laboratories, with regional university hospitals, clinics and teaching centers. All of the professional skills of the region—of physicians, dentists, nutritionists, nurses, technicians, health officers, educators, etc.—would be mobilized for the care of the mothers and children who live there. To make this plan operate, an efficient system of transportation is highly essential.

IV. Every effort should be put forth to acquaint parents in these communities and states with the facilities which now exist, so that they may secure as many of these services as possible for themselves.

V. Federal grants-in-aid should be distributed according to the needs of the state, keeping in mind that the states with lower average incomes have higher ratios of children to adults and require larger proportional grants. When federal grants are used for health services for mothers and children in a state, the citizens and professional groups, through local, regional and state planning councils, should have studied the need and worked out a long range "blueprint" for meeting it. The extent to which such a long range "blueprint" can be put into practice at the outset will depend on the availability of professional workers with experience and competence and on the money available at the time. These factors should provide the basis in any state or community for determining what care shall be provided and for whom. These factors should also provide the basis for estimates by each state and community as to the extent of need for increased funds and additional trained personnel to carry into practice the successive steps of the long range "blueprint." The long range aim of every local, regional or state plan should be to assure that eventually the full scope of health and medical care will be available to all mothers and children, starting with the improvement of existing facilities, adding services step by step within a code of basic standards to be agreed on by experts representing all branches of health and medical care.

VI. Health services for mothers and children provided under public auspices should be centered in one health agency. Good care can result only from a continuity of service in health and disease, in home, in school, in health center, in hospital.

VII. There is need for well-supported and continuing activity in the federal government of a multifunctional agency drawing from the fields of health, education, labor and public welfare for the purpose of investigating and reporting on all matters relating to children and child life. It should cooperate with public and private health and welfare agencies in promoting the well being of the nation's children.

First Steps for Action

Proposed legislation before Congress is to be considered in the light of these points of agreement, plus whatever points might be added from time to time. If proposed legislation is introduced piecemeal, each bill is to be considered as part of a pattern and should fit into other legislation without need for major revision later.

In the present state of agreement, the following first steps are ready for support and action:

1. To establish in every full-time local health unit an organized program of maternal and child health staffed by competent professional workers.
2. To increase governmental appropriations where necessary for existing types of maternal, child health and crippled children services in the states. The purpose of these appropriations should be to upgrade existing maternal and child health and crippled children services with emphasis on encouraging various types of research and demonstration for bringing the best care to an increasing number of mothers and children.
3. To extend research in child life by making available adequate funds to the Children's Bureau to strengthen and broaden its work as a center of information related to child life, and to assist in financing specific study in the field by universities, schools, child research centers, agencies and individuals.

Out of the $625,000,000 spent for research by the federal government in 1947, probably less than $1,000,000 was spent for research in child life. There is great need for more knowledge about how normal children grow and develop in body and mind and the relation of the emotions to this process. The impact of conditions in the family, such as relations between parents and children; of attitudes of the physician and nurse as they provide medical and health care toward their child patients; the effect of customs and attitudes on the mind and health of the child as he grows—these and many other factors of similar nature are not fully understood and their relation to health is unmeasured. The causes and care of a number of diseases of children are still in need of much research in which the combined efforts of voluntary agencies, universities, other research centers and the local, state and federal governments are urgently needed to bring about a speedy solution.

Research is also needed in the various forms of organization for providing health and medical care in communities, states and the nation. The effectiveness of health education on the health habits of mothers and children is still largely untested.

4. To make possible the continued education of private practicing physicians, public health workers, nurses, dentists and other professional workers.

Mothers and children can receive adequate health and medical care only as more competent and experienced professional workers are available in private practice, in hospitals and clinics, schools and laboratories and in the various government services. Additional governmental and other financial support is needed for: fellowships and scholarships granted to professional workers; development of training courses and institutes for the continuous education of professional workers on the job using regional specialists wherever possible.

STATEMENT OF PRINCIPLES FOR THE IMPROVEMENT AND BETTER DISTRIBUTION OF NURSING SERVICES

The achievement of the following objectives is essential for the improvement in quantity, quality and distribution of nursing personnel in this country.

I. Expansion, improvement and financial support of nursing education in order (a) to attract greater numbers of qualified candidates, and (b) to prepare those nurses presently practicing as well as student nurses to meet rapidly changing medical and social demands.

II. Licensure of all who practice as graduate, trained, registered, practical or "licensed practical nurses" in order that safe nursing care will be assured to the public. (No attempt will be made to require licensure of various auxiliary workers, such as nursing aides.)

III. Promotion of such economic and other conditions of employment as will attract and retain an adequate number of competent nursing personnel.

IV. Research in nursing service practice is fundamental in determining the functions of various categories of nurses so that nursing resources can be utilized more effectively.

V. Intensive recruitment both national and local of students for schools of nursing.

VI. Development of sound training programs for auxiliary personnel.

STATEMENT ON LOCAL HEALTH UNITS FOR THE NATION

The principle of national health protection through tax-supported public health services within the jurisdiction of units of local civil government is approved.

The basic functions of such units or combination thereof, are *at least* the following six: Vital Statistics; Communicable Disease Control; Environmental Sanitation; Public Health Laboratory Service; Maternity, Infant and Child Hygiene, including children of school age; Public Health Education.

Additional functions are now included in some communities and a well rounded program will add still others. Among these are the prevention of chronic disease, dental health, mental health, occupational health, accident prevention, provision of hospital and medical care for selected groups for which there is acknowledged community responsibility.

Action Steps

I. Each professional organization interested in the field of health can with advantage concentrate its first efforts towards the formulation within each state of a well considered overall plan for the location, organization, staffing and tax support of local health units. It is estimated that 1,200 units will be sufficient for the nation.

II. The second and quite as pressing obligation is to promote public understanding of the best methods for improving the health of the people to the end that popular support of such achievement will become effective through the voluntary organizations, the members of the health profession and the officers and personnel of local government.

III. A third opportunity is the setting of high merit standards for public servants from among the professions and technologies involved with a view to encouraging the recruitment of competent personnel and the payment of salaries that will attract men and women of high quality.

IV. It is important for the success of many efforts toward the improvement of public health that the weight of all interested organizations be placed behind the movement to secure complete coverage of the nation with modern public health service.

Twelve Point Program

The special committee of the Board of Trustees to study the Twelve Point Program, which was appointed in compliance with a recommendation of the Reference Committee on Legislation and Public Relations at the San Francisco Session in 1950, has had several meetings and has given the program a great deal of serious consideration. A report is being prepared for submission to the House of Delegates.

Public Relations Department Expansion

As was reported to the House of Delegates at the Cleveland Session in December 1950, a committee consisting of Dr. Gunnar Gundersen, Chairman, Dr. Edwin S. Hamilton and Dr. B. R. Kirklin has been studying the public relations facilities and program of the Association. The committee has made recommendations to the Board of Trustees, which have been carried out, so far, as follows:

Mr. Lawrence Rember, heretofore Director of the Department, is now Field Director and spends a great deal of his time on the road bringing the Association's message to the "grass roots" in all parts of the country, advising local and state medical societies as to ways and means for expanding and improving their activities in public relations and gaining information of value to the headquarters offices.

Mr. Leo Brown, who came to the American Medical Association in December 1950 from his position as Public Relations Director for the Medical Society of the State of Pennsylvania to serve as Executive Secretary of the Student American Medical Association, has been placed in charge of the Public Relations Department as Director.

A forward step in the over-all set-up is the appointment about a month ago of an Advisory Committee to the Director of the Public Relations Department, composed of executive secretaries or public relations directors of constituent state medical associations. The members of this advisory committee are:

Mr. Charles S. Nelson, Executive Secretary, Ohio State Medical Association.

Mr. Ray E. Smith, Executive Secretary, Indiana State Medical Association.

Mr. Hugh W. Brenneman, Public Relations Counsel, Michigan State Medical Society.

Mr. Harvey T. Sethman, Executive Secretary, Colorado State Medical Society.

Mr. John Hunton, Executive Secretary, California Medical Association.

Mr. Richard H. Graham, Executive Secretary, Oklahoma State Medical Association.

Mr. Charles H. Crownhart, Secretary, State Medical Society of Wisconsin.

Mr. Frederick W. Miebach, Director, Public Relations Bureau, Medical Society of the State of New York.

The Advisory Committee will hold its first meeting *during* the Annual Session in Atlantic City.

Another forward step looking to a more efficient and comprehensive department is the appointment of an *Intradepartmental* Public Relations Committee for the purpose of *coordinating* all public relations activities of the headquarters staff.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. E. V. Allen, Chairman, presented the following report, which was adopted section by section and as a whole:

Your committee has reviewed those portions of the Report of the Board of Trustees referred to it, and has taken the following action:

1. Exemption From Membership Dues: Your committee approves the action of the Board of Trustees in regard to this matter.

2. Public Relations Department Expansion: Your committee approves the action of the Board of Trustees in regard to this matter.

3. Student American Medical Association: Your committee approves the acceptance of this portion of the report. Your committee notes with approval the attendance in this House of Delegates of Mr. Warren Mullen of the University of Michigan and Mr. Harry Sandberg of the University of Illinois. Your committee also commends the activities of the Student American Medical Association, and expresses the hope that it will continue to grow in scope of activity and in number of participants.

4. Appointment to Membership on Council on Scientific Assembly: Your committee approves the action of the Board of Trustees in regard to this matter.

5. Resolution on Absentee Ballot Adopted at Cleveland Session: Your committee approves acceptance of this portion of the report.

6. Treasurer's Report and Auditor's Report: Your committee approves the acceptance of this portion of the report.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, presented the following report, which was duly adopted after discussion and as amended by the following statement of Dr. E. Vincent Askey, California, concerning the portion on Hospital Standardization:

At all times the Board of Trustees or the representatives of the American Medical Association be instructed, in any agreement they make to be bound and to follow the principles as elucidated by this House of Delegates.

Aid to Medical Schools for Construction Only: Your Reference Committee on Medical Education and Hospitals wishes to report on that portion of the Report of the Board of Trustees referring to "Aid to Medical Schools for Construction Only."

The committee took the liberty of rephrasing this statement of policy for the sake of clarity and suggests the following statement:

The policy of the American Medical Association shall be the endorsement of the principle of a one-time federal grant-in-aid on a matching basis, based on the Hill-Burton Act formula and administrative machinery, for construction, equipment and renovation of the physical plants of medical schools. No part of the funds shall be used in any manner for operational expenses or salaries.

Hospital Standardization: Your Reference Committee on Medical Education and Hospitals wishes to report on that portion of the Report of the Board of Trustees referring to Hospital Standardization; the resolution presented by Dr. C. A. Nafe for the Indiana delegates, entitled "Appointments to the Commission on Accreditation of Hospitals"; the resolution from the Nebraska State Medical Association recommending that "Control of Professional Standards in Hospitals be Vested in the American Medical Association"; the resolution presented by Dr. George Earl for the Minnesota delegates on "Hospital Standardization Program" recommending that the American Medical Association singly or in combination with the American College of Surgeons continue to maintain the Hospital Standardization program in its traditional form, and the resolution presented by Dr. Ralph A. Johnson for the Michigan delegation, entitled "Hospital Standardization" recommending that the American Medical Association extend inspection service to include the inspection of all portions of hospital care and looking to the standardization of hospitals inviting the cooperation of any other national organizations which have an interest in this problem. In addition, your committee had the Supplementary Report of the Board of Trustees signifying that that body has received an invitation from the American Hospital Association for a conference between officials of that Association with the Board of Trustees of the American Medical Association for a preliminary discussion of hospital-physician relationships. They have voted that arrangements be made to hold this meeting in the near future.

During an extended hearing, your committee listened to many views ranging from support of the Board of Trustees report, to limiting the organizations on the accrediting body to 3, 2 and even one; suggestions that the accrediting agency represent any one medical organization just as long as two or more general practitioners were included in its personnel; or that the one organization be the American Medical Association, and that only professional medical organizations be represented on the Commission.

It was a difficult problem and your committee thinks everyone is cognizant of the work of and are grateful to our Board of Trustees for the emergency handling of a delicate problem in an efficient manner.

In spite of the various views expressed, many showing fear or suspicion of one or another group, both within and without the profession, and after listening to the details of background and methods of arriving at the Board's present report, your committee sympathizes with those groups who would like to bring this problem more nearly or even completely under control of our own organization.

Your committee wishes to make it clear that it has learned that the other proposed cooperating organizations each will contribute a proportionate financial support, in spite of the willingness of our Board to assume the whole financial burden. Therefore, we realize that financial aspects cannot accomplish a complete solution.

It appears to us that failure on our part to share in some proportion the over-all great responsibility of the proposed agency at this time may bring discredit, possible suspicion and perhaps other complicating difficulties to our organization.

Your committee believes that the negotiating committee of the Board of Trustees has performed a splendid service in gaining an increase in voting power for Doctors of Medicine on the Commission gradually from the original ratio of three out of twenty-four, to twelve of eighteen, and for the American Medical Association to six of eighteen. A large number of members in their discussion before your reference committee expressed a desire for an even greater proportion in the voting power of the American Medical Association on the Commission. Your committee has learned nothing that either the negotiating committee or the Board of Trustees themselves did not wish the same. Indeed, we believe there is a possibility that they did desire it, as shown by the increasing augmentation in this respect from the original proposal to the present one. Therefore, we believe that this House of Delegates should further support the Board of Trustees by recommending that they rearrange slightly the voting power in the Commission to: Three representatives of the American College of Surgeons; three representatives of the American College of Physicians; four representatives of the American Hospital Association, and eight representatives of the American Medical Association.

By such an arrangement, an evolutionary process, together with our belief in the astuteness and continued diligence of the Board of Trustees, your committee believes we can assure those with opposing resolutions and testimony that the best interests of all divisions of the medical profession will be amply protected.

Your committee wishes to call to the attention of the Board of Trustees the desirability of expressions repeatedly made in discussions before them, that general practitioners be represented on the voting body for the American Medical Association and that an advisory committee be formed consisting of representatives from all scientific sections of the American Medical Association. To implement these, your committee recommends that the House of Delegates request that the Board of Trustees should institute these suggestions, and that they make it permissible for members of the advisory committee to observe the deliberations of the Accreditation Commission, a provision which would allow present consultants from all medical fields when problems concerning them arise.

This committee wishes to call to the attention of the Board of Trustees the desirability of statements which were also so frequently expressed, that inspections, discussions and accreditation of hospitals by the Commission from the point of view of the medical professional aspects of hospital care be carried out only by the medical representatives on the Commission, and that they convey this philosophy to those representatives after the Commission has been formed to be implemented when and as soon as it could be possible to do so.

It is anticipated that the Board of Trustees and later, the American Medical Association representatives on the Commission, will inform the House of Delegates, through the report of the Board of Trustees during meetings of the House of Delegates, of the progress toward implementation of these evolutionary recommendations.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. William R. Brooksher, Chairman, presented the following report which was adopted:

That portion of the report of the Board of Trustees entitled "Inter-Association Committee on Health" was considered by your committee. Your committee does not now recommend adoption of the statements but does recommend a continuation of the activities of this committee in cooperation with the other organizations comprising the Inter-Association Committee on Health.

SUPPLEMENTARY REPORT OF BOARD OF TRUSTEES

Dr. Louis H. Bauer, Chairman, presented the following supplementary report of the Board of Trustees:

1. Contributions to Medical Schools: The Board of Trustees wishes to reiterate that any physician who desires to earmark his contribution to the American Medical Education Foundation for a specific medical school may do so and that the medical school will be so informed when the funds are turned over to it.

2. Meeting with American Hospital Association: An invitation has been received from the American Hospital Association for a conference between the officials of that Association with the Board of Trustees of the American Medical Association for a preliminary discussion of hospital-physician relationships. The Board of Trustees voted that arrangements be made to hold this meeting in the near future.

3. Committee on Nervous and Mental Diseases: Cognizance was taken of the fact that the American Medical Association has no committee on mental health. The Board of Trustees, therefore, authorized the appointment of a Committee on Nervous and Mental Diseases.

4. Advisory Committee on Internships: The Board of Trustees, believing that it should undertake at this time an intensive study of the problem of the discrepancy between the number of internships offered and the number or available candidates and the question of the possible alteration or abolishment of the internship, approved the appointment of an advisory committee to the Council on Medical Education and Hospitals, to be composed of leaders in the field of education, practice and hospital administration, and has appropriated sufficient funds to permit the committee to function.

5. Resolutions on National Broadcasting Company:

WHEREAS, The National Broadcasting Company is celebrating in 1951 the twenty-fifth anniversary of its service to the American people; and

WHEREAS, The National Broadcasting Company has rendered outstanding educational services to the American people through its broadcasting of public events, music, literature, forums and other educational features; and

WHEREAS, Health education has been among the principal interests of the National Broadcasting Company manifested through its cooperation with the American Medical Association from 1933 until the current year 1951 through seventeen annual series of pioneer broadcasts demonstrating the application of the dramatic technique by radio to the advancement of health education and by other broadcasts; and

WHEREAS, These broadcasts have constituted an outstanding service to the American people and have represented a high degree of cooperation with the medical profession in the pursuit of common objectives; therefore be it

Resolved, That the American Medical Association, by action of its House of Delegates assembled at Atlantic City, June 11, 1951, does hereby offer to the National Broadcasting Company its congratulations on the completion of a quarter century of outstanding public service; and be it further

Resolved, That the American Medical Association extends to the National Broadcasting Company its sincere expression of appreciation for cordial cooperation and effective teamwork in health education by radio.

6. Resolution on Income Tax Exemption: This resolution, introduced by Dr. J. Wallace Hurff of New Jersey, amended by the Reference Committee on Legislation and Public Relations and adopted by the House of Delegates in June 1950, was referred to the Committee on Legislation.

The Committee gave consideration to it and reported that the present holding with respect to the deductibility of the expenses under consideration is based on a ruling of the Office of the Commissioner of Internal Revenue, which is as follows: "Expenses incurred by doctors in taking postgraduate courses are deemed to be in the nature of personal expenses and not deductible."

Efforts have been made since 1925 to have this ruling reversed but have not been successful. The Committee on Legislation recommended that if and when it is considered timely and desirable to prosecute this matter further there are available at least three methods of approach. First, an effort could be renewed to induce the Office of the Commissioner of Internal Revenue to reverse the 1921 ruling. Secondly, further efforts could be made to bring the issue before the United States Tax Court, with the assumption by the Association of all expenses incident to the appeal, and finally, if the two approaches suggested are without results, an attempt could be made to induce the Congress to amend the Internal Revenue Code specifically to authorize the deductibility of expenses incurred in pursuing postgraduate study.

The Board of Trustees approved the report of the Committee on Legislation and directed that another effort be made to induce the Office of the Commissioner of Internal Revenue to reverse the 1921 ruling and, if that fails, to endeavor to bring the issue before the United States Tax Court.

7. Report of Committee on the Twelve Point Program: On June 28, 1950, in San Francisco, the Reference Committee on Legislation and Public Relations of the House of Delegates in its report expressed the opinion that the Twelve Point Program should be augmented and clarified. The Committee recommended that "The House of Delegates request the Board of Trustees to appoint a committee to study carefully the Twelve Point Program, with the idea of making changes which may be indicated." The Committee further recommended that "this be a continuing committee which will advise the Association from time to time concerning appropriate changes in policy which may be deemed advisable, by changing circumstances." This report was adopted by the House of Delegates. In accordance with this directive, this Committee was appointed by the Board of Trustees and has been engaged in a diligent study of the Twelve Point Program and related questions of policy. Advice has been sought and received from many individuals and groups, including a number of departmental heads of the American Medical Association headquarters. Reports have been rendered the Board at its quarterly meetings in December, February and April. Full agreement has not been reached by the Board in reference to a number of questions of policy recommended in these reports and it is felt that such debatable matters should have further consideration before a final report is rendered to the House of Delegates by the Board of Trustees.

It is further felt that the purposes of the committee should be further defined. The implications of the directive from the House of Delegates are that the Committee should not only augment and clarify the Twelve Point Program but should recommend policies or changes in policies as would serve to carry out the purposes expressed therein. We believe that this intent should be clearly affirmed or denied by the House of Delegates.

We are satisfied that the Twelve Point Program, as originally formulated and as further elucidated, constituted a satisfactory statement of our objectives. Certain of these objectives have been accomplished in whole or in part. Others are now in controversy. Our fundamental policy is expressed in our Constitution and our Principles of Medical Ethics. Article 2 of our Constitution states that "the objects of our Association are to promote the science and art of medicine and the betterment of public health." Any elaboration of this simple and comprehensive statement would seem useless.

There are, however, certain practical questions requiring action. Numerous bills are introduced into each session of the Congress, affecting medicine in its several branches and the medical welfare of the public at large. In testifying before the Committees of the Congress, it is not sufficient to quote our Twelve Point Program or Article 2 of our Constitution.

It seems necessary, therefore, to formulate certain practical policies that will guide us in striving to accomplish our own objectives as expressed in our Twelve Point Program, and in supporting or opposing proposed legislation bearing on medicine.

We feel that such a statement should define the components of good medicine and enumerate the safeguards and restrictions that should be included in any bill before the Congress that may affect the medical welfare of the American people. We therefore recommend to the Board of Trustees that it request the House of Delegates to define the purposes of this committee, and that this committee or its successor be authorized to formulate such a statement of policy to be presented to the Board of Trustees for its consideration and recommendation to the House of Delegates.

8. Proposed Amendment to By-Laws: The Board of Trustees recommends the following amendment to Chapter X, Section 4, fourth paragraph under "(B) Membership" to read:

"The Council on Medical Service shall include nine Member or Service Fellows, each of whom shall serve for a term of three years so arranged that at each annual session the terms of three members expire. In addition, the immediate Past President of the Association shall serve as a member of the Council. At each annual session the Board of Trustees shall present to the House of Delegates three nominations for each vacancy in the Council, and the House of Delegates shall elect from such list. In 1951 three members shall be elected for three years, one for two years and one for one year. The chairman shall be selected by the Council from its elected members."

9. Informative Report on Advisory Committee of Outstanding Laymen: The Board of Trustees is very anxious to see the Association improve its relations with the general public. We feel that perhaps we do not come quite close enough to the general public and we also feel that the Association, we as a profession, should anticipate the needs of the public. Therefore, the Board voted this morning that it would appoint an advisory committee of outstanding laymen who will meet with the Board from time to time and give it advice on the reaction of the public to various propositions, and perhaps bring matters to our attention which we otherwise might not hear about soon enough.

May I say that, in making up this committee, we have not settled on any definite number. There will be no politicians on the committee, but those who are selected will be men of such outstanding prominence that their very names will inspire public respect. We feel this in itself is going to help improve the public relations of the Association. We have in mind picking people from industry, both large and small, from the bar, from education and from the clergy, and possibly others. We have not yet determined the details of it but we feel it is a very forward step in improving the relationship between the American Medical Association and the general public.

RETIREMENT OF HATTIE A. NIEHOFF

Before I sit down, I would like to say just one word which is not part of my official report. We have here on the platform this morning an individual who has served the American Medical Association for thirty-seven years and she has been the chief clerk of this House of Delegates for I don't know how many of those thirty-seven years, certainly long before I became officially connected with the American Medical Association. She is retiring in September so this is the last function at which you will see her officially, but I hope she will return unofficially and watch us trying to struggle along without her.

I think that the House should give a standing testimonial to Miss Hattie Niehoff for thirty-seven years of faithful, devoted, loyal service.

May I say, in closing, that I wish every member of the American Medical Association was as inspired with loyalty to our Association as she has been.

The Speaker referred to the Reference Committee on Reports of Board of Trustees and Secretary the supplementary reports of the Board of Trustees on Contributions to Medical Schools, Resolutions on National Broadcasting Company and report of Committee on Twelve Point Program; to the Reference Committee on Medical Education and Hospitals the reports on meeting with American Hospital Association and Advisory Committee on Internships; to the Reference Committee on Miscellaneous Business the report on Committee on Nervous and Mental Diseases; to the Reference Committee on Legislation and Public Relations the Resolution on Income Tax Exemption; to the Reference Committee on Amendments to the Constitution and By-Laws the Proposed Amendment to Chapter X, Section 4 "(B) Membership."

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Edgar V. Allen, Chairman, presented the following report, which was duly adopted section by section and as a whole:

1. Contributions to Medical Schools: Your committee agrees with the Board of Trustees that emphasis should be placed on the fact that physicians who desire to earmark their contribution to the American Medical Education Foundation for a special medical school may do so, and that the medical school should be so informed when the funds are allocated to it, and recommends that this privilege be publicized in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and brought to the attention of the constituent state medical associations. Your committee notes with approval that the American Medical Association, through its Board of Trustees, absorbs the cost of allocation of such funds.

2. Resolutions on National Broadcasting Company: Your committee concurs with the Board of Trustees that a congratulatory resolution be sent to the National Broadcasting Company in commemoration of its 25th anniversary.

3. Report of Committee on Twelve Point Program: Your committee has reviewed the report of the Board of Trustees on the Twelve Point Program as well as the supplementary report of the Board of Trustees on this same subject. It is the recommendation of your committee that the special committee which was constituted by the Board of Trustees to review and augment the Twelve Point Program as authorized by the House of Delegates at the 1950 Session in San Francisco be empowered to formulate a statement of policy that will guide the Association and its constituent societies in implementing the Twelve Point Program and in dealing with legislative proposals affecting the medical welfare of the American people.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, presented the following report which was duly adopted section by section and as a whole:

1. Meeting with American Hospital Association (See report under action on Report of Board of Trustees).

2. Advisory Committee on Internships: Your Reference Committee on Medical Education and Hospitals wishes to report on that portion of the Supplementary Report of the Board of Trustees, referring to an Advisory Committee on Internships.

Your committee commends this action of the Board of Trustees and appreciates its implementing appropriation for this much needed evaluation of a multi-faceted and important phase of medical education.

Your committee further recommends all possible speed compatible with ability to reach sound conclusions and make definite recommendations. A report of the status of this investigation should be made to the next session of this House of Delegates in Los Angeles in December, 1951.

As any constructive answers to the Illinois State Medical Society's Resolution on the More Equitable Distribution of Interns to Small Non-Teaching Hospitals, and the resolution from the Ohio State Medical Association concerning this same problem, are dependent on the investigation being instituted by the Board of Trustees, this committee commends those societies for their constructive thinking. It recommends serious consideration by the Advisory Committee of our recommendation for speed. The present cooperation between the Council on Medical Education and Hospitals and the official governing bodies of interns in the various states, as well as the present vicious financial bidding for intern services are dependent on an early solution by this new investigating committee.

Report of Reference Committee on Miscellaneous Business

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

Supplementary Report of Board of Trustees on Committee on Nervous and Mental Diseases: Your reference committee approves of the action of the Board of Trustees in authorizing the appointment of a committee on nervous and mental diseases.

Report of Reference Committee on Legislation and Public Relations

Dr. L. G. Christian, Chairman, presented the following report, which was duly adopted:

Resolution on Income Tax Exemption: Your committee approves the report as written and suggests that effort be made to induce the Department of Internal Revenue to reverse the 1921 ruling, which is: "Expenses incurred by doctors in taking postgraduate courses are deemed to be in the nature of personal expenses and not deductible," and report to the House of Delegates at its interim meeting in Los Angeles in December, 1951.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Robertson Ward, Chairman, presented the following report, which was duly adopted:

Amendment Proposed to Chapter X, Section 4(B) Membership: A supplementary report of the Board of Trustees, introduced by Dr. L. H. Bauer, concerning a change in the composition of the Council on Medical Service, was considered by your committee. After considerable discussion, in which the reasons for the suggested amendment were explained by the Board of Trustees, it is the recommendation of your committee that this resolution be not accepted, and that a substitute resolution be adopted. The substitution is as follows:

Resolved, That a special committee of the House of Delegates be appointed by the Speaker to review the organizational structure of the standing committees of the House of Delegates, especially in their relation to the Board of Trustees, and report to the House of Delegates at the next interim session in Los Angeles.

Report of Secretary

Dr. George F. Lull, Secretary, presented the following report which was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

To the Members of the House of Delegates:

According to the instructions of the House of Delegates, the Secretary renders an annual report but once a year, and that report is rendered at the midwinter session, the Clinical Session. I have no supplemental report to render. However, I have some remarks to make about the dues.

The dues are being paid in an extremely gratifying manner. We are going to have for the year 1950 well over 90% of the dues-paying members of the Association having paid their dues. We find, of course, that a great many people who have been carried as members are, in reality, not dues-paying members. Some of them are very old and are not engaged in the practice of medicine; others are interns and residents, honorary members in some places; and we have been unable to determine until the present, and it is not wholly determined at the present time, as to just who they are. We have carried them as members and when they did not pay the 1950 dues and we sent a letter, we received a reply saying, "I am 87 years of age and I do not practice."

We have some members who say they never were members of the Medical Association and they have not understood for years that they have belonged to the American Medical Association because they have never had to pay any dues. They say they never joined. We are trying to make that clear to them.

This is a slow process, this change-over in the collection of dues, and it will take a period of several years before we get it on any kind of even keel. The fact that we cannot send out Fellowship bills until membership dues are paid makes it complicated for some who are concerned about getting Fellowship cards. However, I want to report to the House that it is very gratifying the way the membership dues are coming in.

Report of Coordinating Committee

Dr. Elmer L. Henderson, Chairman, presented the following report, which was referred to the Reference Committee on Miscellaneous Business:

Mr. Speaker, Members of the House of Delegates:

Earlier today, during the President's address, you heard the announcement of the Coordinating Committee and the Board of Trustees, that the National Education Campaign will be terminated at the end of 1951, on the recommendation of Whitaker and Baxter, the campaign managers. The remainder of this year will be a transition period during which the Public Relations Department of the American Medical Association should position itself to maintain the great gains made in public support during the campaign. Your Coordinating Committee, which has been charged with the general supervision of the National Education Campaign since its inception, feels therefore that this is an appropriate time to review briefly the progress of our work.

As we taper off our campaign activities in this period of comparative calm, the medical profession can look back with pride on its achievements during the past two and one-half years of fire and fury. We have come a long way in our battle against socialized medicine. We have struck some strong, positive blows in behalf of American freedom and voluntary methods, and perhaps we have made a little history in the process.

When we began our campaign in January, 1949, we stood with our backs to the legislative wall, and we stood there alone. But we had a strong case to present and a story to tell that was of imperative importance to the health and welfare of the nation. We presented our case and told our story, not in the political back rooms and horse-trading centers of Washington, but immediately and directly to the American people. The response of the people has shown that organized medicine never has made a wiser decision in the realm of public policy, than to take its case to the people. By the time of our annual session here in Atlantic City two years ago, more than 800 national, state and local organizations had risen up in official protest against compulsory health insurance, and the dismayed advocates of socialized medicine already were beginning to falter. We could scarcely believe that such broad support could be mobilized so quickly.

But that was only the beginning. Since then, with medicine's campaign reaching out to all the nation on a nonpartisan, grass roots basis, the socializers have continued to retreat, and the medical profession has won ever-growing public support. As of now, nearly 11,000 national, state and local organizations, after studying the pros and cons of the issue, are on public record with resolutions against compulsory health insurance or any other form of socialized medicine. Representing many millions of members, and constituting the biggest nonpartisan cross section of opinion ever mobilized on a public issue of this kind, those 11,000 organizations include women, farmers, veterans, businessmen, workers, professional people, educators, clergymen, Democrats and Republicans, rich and poor. Out of their vigorous, public protest against socialized medicine, has come an ever-expanding public opposition to all forms of creeping socialism in this country, a growing realization that the forces of statism threaten not just doctors but all Americans.

Medicine's crusade for freedom and for high medical standards has served not only the medical profession, but the entire Nation. It has rekindled a faith in fundamental Americanism. It has bolstered the courage and spirit of other professions, of businesses and industries and of millions of individuals who would like to preserve the American way of life. Our campaign gave them a rallying point and a means of expression. Last October, for example, when we conducted our intensive, nationwide advertising program, we received outside support in such fabulous proportion that it wrote a new chapter in the field of advertising and public relations.

We ourselves, using newspapers, magazines and radio, spent around one million dollars to state American medicine's position on the basic issue of freedom versus compulsion, voluntary methods versus totalitarian methods. But at the same time more than 65,000 companies, groups and individuals outside of the medical profession spent over two million dollars for tie-in advertising space in which to voice their support of medicine's position. They spent that money, out of their own pockets and of their own free will, to express their confidence in our profession and to reaffirm their faith in the American way of doing things. The most heartening aspect of all was that the vast majority of those advertisers were small companies and individual merchants and businessmen located in the small towns of the nation. Their voice was not the voice of big business or big money. It was the voice of John Q. Public, the voice of Mr. and Mrs. Average American. The same voice was heard again last November in the polling places of the nation, after the votes were counted in the Congressional elections. And again the results reflected public confidence in medicine's campaign against state socialism. The people rejected nearly ninety per cent of the candidates who still were known to favor compulsory health insurance. They rejected a number of others who attempted to straddle or avoid the issue. In both the primary and general elections last year, the people also voiced a general protest against the extension of socialistic philosophies in this nation's government.

Meanwhile, in the positive phase of our National Education Campaign objectives, voluntary programs of all kinds have moved ahead with marked, accelerated progress in the fields of health insurance, medical care, medical education and related activities. Individual physicians and their medical societies in 48 states and over 2,000 counties are engaged in the most constructive, progressive and concentrated programs the nation ever has seen to solve the problems of medical care.

Our long-range campaign goal, you will remember, was not just to beat a bill in Congress, but rather to solve existing problems, meet the medical needs of the people and improve the public relations position of the American Medical Association and medicine generally. The major portion of the campaign funds have been spent for this constructive purpose.

The country's Voluntary Health Insurance Plans are continuing to gain public acceptance as the sensible, American way of taking the economic shock out of the cost of serious illness. At an extremely conservative estimate, at least 72 million Americans now have some form of coverage protecting them against hospital, surgical, or medical expenses. The voluntary plans are working toward an expected total enrolment of 90 million persons within the next two or three years. They not only are growing in size; they also are extending their benefits and improving and simplifying their methods of enrolment on a sound, actuarial basis.

We of the medical profession must continue to give maximum support to the further development of voluntary health insurance to the end that sound, low-cost, comprehensive protection will be available to every American, regardless of where he lives or works.

Progress, the voluntary way, has not been limited to the field of health insurance. The state and county medical societies, with the cooperation of medical schools, public officials and the people in their areas, are demonstrating the value and effectiveness of local effort and cooperation in the field of public welfare. They are making notable progress in establishing programs to provide night and day emergency medical service, to settle the grievances and complaints of patients, to locate doctors and medical facilities in communities which need them, to set up informational services and to improve physician-patient relationships.

In the course of our campaign—presenting the case against compulsory methods, aiding the progress of voluntary methods and telling medicine's story—we have distributed approximately 100 million pamphlets, and other millions of leaflets, stickers, basic speeches, radio scripts, reprints, study and discussion kits, posters, cartoons, articles and other special materials. There is no question that the majority of the people have heard medicine's case and have reacted to the facts. Included in that massive distribution have been almost 90,000 reproductions of the campaign theme piece, "The Doctor" picture, for display in physicians' waiting rooms, hospital lobbies and other appropriate places. More than half of the physicians of the Nation are displaying the picture in their offices, at their own request.

The team of active campaign workers distributing pamphlets, giving speeches, writing letters, talking to friends and fellow citizens and securing formal action from organized groups has been made up of about 250,000 physicians, dentists, druggists, insurance men, doctors' wives and other medical and nonmedical people who believe in our cause.

As a result of that nationwide effort, we have won unmistakable support from the majority of the people. They have expressed that support in many and varied ways, as individuals and as organized groups, through personal letters and official resolutions, by means of newspaper advertising and the ballot box, in public opinion surveys and in the rising enrolments of voluntary health insurance plans.

An especially significant campaign development in recent months, since you last heard a report from the Coordinating Committee, has been the increasing evidence of labor support for medicine's stand against compulsory health insurance. During the Cleveland Clinical Session last December, we heard the vigorous address of Mr. William L. Hutcheson, General President of the United Brotherhood of Carpenters and Joiners of America and Vice President of the American Federation of Labor, in which he reported his union's refusal to support the Truman Health Program, and in which he presented a blistering indictment of socialized medicine. This evening, here in Atlantic City, the House of Delegates will hear an address by another outstanding American labor leader, Mr. Dave Beck, Executive Vice President of the International Brotherhood of Teamsters. Mr. Beck will speak at the dinner meeting to be given by the Medical Society of New Jersey, and his address, like that of Mr. Hutcheson, will be broadcast nationwide. Your Coordinating Committee is confident that Mr. Beck's address will be of great interest, not only to the medical profession but also to the rank and file of American labor and to the general public. The Committee is in a position to predict that the coming months will bring still more concrete evidence of American labor's distaste for compulsory health insurance.

Another recent development, signifying medicine's increased influence in public affairs, and also demonstrating the need for our constant vigilance, was the successful outcome of our clash with Federal Security Administrator Oscar Ewing in the controversy involving the FSA pamphlet, "Common Human Needs." That pamphlet contained the statement: "Social security and public assistance programs are a basic essential for attainment of the socialized state envisaged in a democratic ideology, a way of life which so far has been realized only in slight measure." Our original protest against that statement, made on the President's Page of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, led to a heated exchange of telegrams with Mr. Ewing. In that exchange we refuted his counterprotests by showing that the pamphlet had been reprinted in 1949, some two years after Mr. Ewing became Federal Security Administrator, and that it still was being distributed up to the time of the controversy. As a result, rather than rewriting or eliminating the offensively un-American passage, Mr. Ewing stopped further publication of the pamphlet and ordered the destruction of all copies still on hand.

In the five months period since December, 52 general mailings have been made from Campaign headquarters to keep medicine's story before the general public, members of Congress, physicians, dentists and druggists, the press and special groups such as labor and women's organizations. The material sent out included the report on our advertising campaign, news releases, speeches by various doctors, study kits and specially prepared material for different types of women's organizations, the labor address by Mr. Hutcheson, speeches and articles on medicine's positive accomplishments and a variety of other items.

Your Coordinating Committee feels, in conclusion, that the National Education Campaign not only has built a nationwide bulwark of friends for the medical profession, but also has laid the groundwork for a continued strengthening of medicine's position in the months and years ahead.

Presentation of Plaque from National Editorial Association

Dr. Elmer L. Henderson, President, stated that it was now his pleasure to present to the American Medical Association a beautiful plaque carrying the commendation of the National Editorial Association, and asked the Speaker of the House to read the plaque, as follows:

The National Editorial Association, April 30, 1951

Elmer Henderson, M.D., President, American Medical Association and Chairman, National Education Campaign.

Dear Doctor:

The following action was taken by the National Editorial Association at the spring meeting in New York, April 19, 1951:

"WHEREAS, We believe that an outstanding contribution during the past year to the cause of individual freedom and the maintenance of our American way of life has been the nationwide campaign by the American medical profession in behalf of freedom for both physicians and the cause of political freedom; therefore, be it

Resolved, That we do publicly commend the doctors of our country for their enlightened contribution to the American way of life and do recognize this public service so ably performed by the American Medical Association, the officers, the Board of Trustees, the Campaign Committee and Clem Whitaker and Leone Baxter who directed the National Education Campaign of the American Medical Association."

Sincerely yours,
Don Eck
General Manager

To the office of George Lull, M.D., Secretary and General Manager, American Medical Association.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

Your reference committee has carefully reviewed the report of the Coordinating Committee and the Board of Trustees concerning the National Education Campaign so ably presented by Dr. Elmer Henderson.

The crusade of the National Education Campaign, so effectively organized and conducted in every detail, has not only served medicine but every phase of American life. A by-product of this Committee's work has been to rekindle hope not only for physicians but for other professions, business, labor, and millions of people who want to keep America the citadel of freedom on earth. Gratitude is indeed due to all those walks of human endeavor who rallied so gallantly to the clear, clarion call of an approaching catastrophe. The concerted effort of everybody proved that the medical profession has the know-how to deliver a powerful blow to any evil force that threatens to harm medical care of suffering individuals. The medical profession has always been and will continue to be a light and haven of refuge for the sick. The report of the Committee is a veritable roster, paragraph by paragraph, of accomplishment never before equalled in such a short time. All people should read the report and meditate on every recitation of the accomplishments. One is repaid by a feeling of courage not to weaken or lose faith when fighting for the right. In the report of the Council on Medical Service one reads, "What are we getting for our twenty-five dollars?" After a survey of the results, it can truly be said: First, there are as yet no balls and chains about the ankles of the American physician and he can still walk with pride and head unbowed; secondly, there are no handcuffs and he can still write prescriptions, even if sometimes unreadable, as freely as a bird can scratch for a worm, and thirdly, there is as yet no cerebral ankylosis or palsies, and he can still think freely, spiritually and scientifically, dictated to only by the milk of human kindness and consideration for the sick in mind and body.

All of these were on the very edge of the precipice of extermination on Jan. 1, 1949, when the Coordinating Committee began functioning. What has been wrought is nothing short of miraculous and for so small a pittance in money. Medical freedom could have been lost, yet so many physicians, even today, do not realize this nor are they grateful for their salvation. Miracles are frequently not immediately explained or appreciated. Nothing more can be said about results of the Coordinating Committee's efforts, and nothing more need be said. History, and other plaques such as presented by the National Editorial Association, will record the accomplishment for posterity.

In closing, your committee wishes to inject a note of warning about tapering off the education activities and vigilance lest we drift into a state of complacency. If this should happen we shall be like the fisherman who gives his line too much slack and loses the big fish which are temporarily on the hook.

Your reference committee approves the report of the Coordinating Committee.

Report of Judicial Council

Dr. Walter F. Donaldson, Acting Chairman, presented the following report, which was referred to the Reference Committee on Miscellaneous Business:

1. During the Clinical Session held at Cleveland, in December, 1950, a resolution was introduced suggesting amendments to the Principles of Medical Ethics, Section 6, Chapter I, which section at that time read as follows:

Sec. 6.—An ethical physician will not receive remuneration from patents on or the sale of surgical instruments, nor profit from a copyright on methods or procedures. The receipt of remuneration from patents or copyrights tempts the owners thereof to retard or inhibit research or to restrict the benefits derivable therefrom to patients, the public or the medical profession. The acceptance of rebates on prescriptions or appliances, or of commissions from attendants who aid in the care of patients is unethical. An ethical physician does not engage in barter or trade in the appliances, devices or remedies prescribed for patients, but limits the sources of his professional income to professional services rendered the patient. He should receive his remuneration for professional services rendered only in the amount of his fee specifically announced to his patient at the time the service is rendered or in the form of a subsequent statement, and he should not accept additional compensation secretly or openly, directly or indirectly, from any other source.

The prescription or dispensing by a physician of secret medicine or other secret remedial agents, of which he does not know the composition, or the manufacture or promotion of their use is unethical.

The resolution referred to suggested that in the fourth sentence the words "for financial gain" be inserted after the words "for patients," and that the remainder of the paragraph be deleted. The reference committee recommended that the resolution, as presented, be not approved, but that the suggestions therein contained be referred to the Judicial Council for further study.

The Judicial Council has considered these suggestions, as well as suggestions with similar objectives received from other sources, and now recommends to the 1951 House of Delegates that Section 6, Chapter I, first paragraph, of the Principles of Medical Ethics be amended to read as follows:

An ethical physician will not receive profit from patents on, or from the sale of surgical instruments, appliances and medicines nor from a copyright on methods or procedures. The acceptance of profit from patents or copyrights tempts the owners thereof to retard or inhibit research or to restrict the benefits derivable therefrom to patients, the public or the medical profession. The acceptance of rebates on prescriptions or appliances, or of commissions from attendants who aid in the care of patients is unethical. It is unethical for a physician to engage for financial gain in barter or trade in the appliances, devices or remedies prescribed for patients. The ethical physician limits the sources of his professional income to professional services rendered the patient. Fee splitting under any guise is unethical.

The Judicial Council has added to the suggestions of last year's reference committee only the last sentence, reading: "Fee splitting under any guise is unethical."

2. Request for reconsideration of 1950 resolution from Section on Ophthalmology: At the 1950 session of the House of Delegates in San Francisco, the House adopted a resolution which, in effect, reversed the 24-year position of the American Medical Association on the ethical question of members of the Association giving lectures or courses of instruction to optometrists.

This reversal was accomplished through the introduction of a resolution in 1950 from the Section on Ophthalmology which "declared that it is entirely within the definition of medical ethics for members to engage in lectures, demonstrations, the preparation of pamphlets, and other measures suitable for the dissemination of information designed to prevent blindness and directed to any nonmedical group." This resolution was referred to the Reference Committee on Miscellaneous Business, which committee returned it, recommending favorable action to the House of Delegates. It was adopted by the latter without discussion.

The Judicial Council sensed the encouragement which this favorable action offers to such groups as the optometrists in seeking, as they constantly do, legislation to expand their field of professional activity more and more into the field of medicine in eye conditions. The Judicial Council brings the subject to the attention of the House at this time, believing that such implications of the resolution favorably acted on last December may not have been fully realized by the reference committee or the 1950 House of Delegates. The Judicial Council requests reconsideration of this decision by the 1951 House of Delegates.

Respectfully submitted,

EDWARD R. CUNNIFFE, Chairman.
WALTER F. DONALDSON.
H. L. PEARSON, JR.
J. B. LUKINS.
LOUIS A. BUIE.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was rejected by the House after discussion:

Your reference committee recommends that the original section and the amended section as recommended by the Judicial Council be disapproved, and that the following substitute amendment be adopted:

The receipt of profit from patents or copyrights on medical appliances or remedial agents which tempt the owners thereof to retard or inhibit research or to restrict the benefits derivable therefrom to patients, the public or the medical profession is unethical. The acceptance of any rebates is unethical. The acceptance of commissions from attendants who aid in the care of patients is unethical. It is unethical for a physician to charge unfair or excessive prices for appliances, devices or remedies prescribed for patients. Fee splitting under any guise is unethical.

Dr. Eggston presented the following report, which was duly adopted after discussion:

Your reference committee after hearing the delegates from the Section on Ophthalmology and a majority of the other ophthalmologists present who were in favor of the resolution as passed by the House of Delegates in 1950, and after consideration of all the implications of possible invasion in the practice of medicine mentioned by the Judicial Council, approves of the action of the House of Delegates taken in 1950.

Report of Council on Medical Education and Hospitals

Dr. Herman G. Weiskotten, Chairman, presented its report which was referred to the Reference Committee on Medical Education and Hospitals (see page 865).

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, presented the following report which was duly adopted:

Your committee highly commends the clear cut declaration of policy and recommends that the Board of Trustees authorize through THE JOURNAL and through the department of public relations the widest possible distribution of this excellent statement.

Introduction of Dr. A. Sharman, Glasgow, Scotland

The Secretary, Dr. George F. Lull, at the request of the Speaker, Dr. F. F. Borzell, introduced Dr. A. Sharman of Glasgow, Scotland, the official delegate from the British Medical Association.

The House recessed at 12:50 p. m. to reconvene at 2:30 p. m.

The House reconvened at 2:35 p. m., with the Speaker, Dr. F. F. Borzell, presiding.

Introduction of Mr. Dave Beck

Dr. Elmer L. Henderson, President, introduced Mr. Dave Beck, Executive Vice President of the International Teamsters Union.

Report and Supplementary Report of Council on Medical Service

Dr. James R. McVay, Chairman, presented the following report and the supplementary report of the Council on Medical Service, which were referred to the Reference Committee on Insurance and Medical Service:

To the Members of the House of Delegates of the American Medical Association:

The work of the Council on Medical Service is a never ending process. It is a process set forth in the Constitution and By-Laws and includes the study and collection of data on various aspects of medical service, reporting changes and trends to the House of Delegates, the constituent associations and component societies and making such recommendations as the Council believes will improve medical care.

In retrospect many results of the activities of the Council can be seen. For example, in 1944 when the Council found a need for the development of public relations programs at the state and county levels, it held the first American Medical Association public relations conference and for several years thereafter stressed the importance of public relations programs at its regional conferences. Today the American Medical Association has its own Department of Public Relations, and most of the state associations have public relations programs. Another example is the Washington Office which was originated by the Council to keep the profession abreast of legislation affecting medicine and to keep legislators abreast of medical progress. Similarly, the American Medical Association Handbook, the Twelve Point Program, and the Student American Medical Association were all originally proposed or developed by the Council. The "Grass Roots" Conference, the Commission on Chronic Illness, the cancer detection program, and the Hill-Burton Hospital Construction program are additional examples of projects supported by the Council to further the objectives defined for it by the House of Delegates. Health centers, state and community health councils, community health leadership programs, voluntary prepayment medical care plans, emergency call programs and the Physicians Placement Service are other examples of activities with which the Council has been concerned. Some of these activities and programs are completed; others require continuing attention. Some activities have been assumed by other groups, but even in these the Council continues to have a practical interest, sometimes to the extent of making recommendations for improvement, sometimes only to the extent of reporting to the House and to the profession.

In order to cover more completely the various aspects of medical service, seven committees were created two years ago to serve the Council in an advisory capacity. The collection and study of information and data on existing services and facilities is a continuous part of the work of each committee. These committees also follow trends in medical service that fall within their particular field and, whenever problems or situations warrant, will make special reports to the Council. The primary objective of each committee is to assist the Council in developing a correlated program covering the entire field of medical service, a program through which the public can benefit best from the accomplishments of American medicine and by which the constituent associations and component societies can be assisted in strengthening their own community programs.

In order that the members of the House of Delegates may be aware of the recent activities of the Council, the following progress report is presented.

"YOU AND YOUR A. M. A."

"What are we getting for our twenty-five dollars?" is a question frequently asked by doctors in regard to the American Medical Association.

To answer this question and many others concerning the activities and plans of the Association, the Council on Medical Service proposes to "take the American Medical Association to each doctor who attends the annual session of his own state medical association."

This is the proposed plan of the Council on Medical Service: to include a period to be known as "You and Your A. M. A." in the program of each state society at its annual session.

The purpose of this program will be to inform those in attendance as to just what the American Medical Association is doing and in turn give the doctors in attendance an opportunity to state just what they would like to see the Association do. In addition to speakers, arrangements call for exhibits where suitable material can be distributed, the use of slides and a moving picture, if it can be developed, highlighting and concentrating on the work of the various Councils, departments, and Bureaus of the American Medical Association. In order that the most effective program possible may be developed, this undertaking will of necessity be with the advice and assistance of the Public Relations Department, the Bureau of Exhibits and other departments at the headquarters offices, and will be a joint effort with the individual state associations.

The Board of Trustees has approved a trial run of the program, and the Council has completed arrangements with four states in which meetings are to be held this fall—Pennsylvania, Colorado, Virginia and Indiana—to test the feasibility of offering such a program as a part of the annual meetings of those societies which may desire such programs.

The Board of Trustees memorandum relative to these four pilot programs reads as follows:

> The general principles underlying the programs submitted by the Council on Medical Service and the general outline of those programs are approved. The Board congratulates the Council on its foresight and enthusiasm.
>
> The Board urges that the various activities of the Council be brought before the doctors of the country as intensively as possible. It realizes, however, that often state societies will request discussions on matters not under the jurisdiction of the Council. It is desirable that, whenever requested, all activities of the Association be properly portrayed. However, the coordination of the activities of the various councils and bureaus and the formation of policies cannot be delegated by the Board. Hence, the final determination of all programs must remain under the jurisdiction of the Board.
>
> In order more effectively to develop and facilitate these programs, the Board delegates authority for the preliminary arrangements of these programs to the Council on Medical Service. The Council should clear and coordinate all such programs with the Department of Public Relations and the Secretary and General Manager.
>
> Whenever the final programs involve activities not within the field of the activities of the Council on Medical Service the meetings should be presided over by an officer of the Association or a member of the Board of Trustees.

COUNCIL COMMITTEES

The Committee on Extension of Hospitals and Other Facilities during the first four months of 1951 has concerned itself with: physician-hospital relations; keeping information on the Hospital Construction Act up to date and correlating it with the data used in the Physicians Placement Service; collecting information and data regarding health centers, diagnostic clinics and outpatient dispensaries and the preparation of loan kits on these subjects for use by interested physicians, and maintaining liaison with the specialty groups, particularly the radiologists, anesthesiologists and pathologists.

As a follow up to the recommendation of the House of Delegates that committees on physician-hospital relations be appointed by both constituent and component societies, the Committee has mailed a copy of the now well known Report of the Committee on Hospitals and the Practice of Medicine to all county medical societies and has made additional copies available on request. In addition, inquiry has been made to determine how many such committees are now in existence. Of the 757 county medical societies replying to the inquiry of the Committee, 263 stated they had a committee on hospital relations. A similar inquiry of the constituent associations has resulted in 33 replies as of May 1. Of these, 30 state medical associations and the District of Columbia have such committees. Two states and Hawaii are without committees, although both of the states indicated that the matter would be discussed during the next meeting of their governing bodies.

In 18 states these committees seem to have been created for the specific purpose of handling hospital and professional relations and for the most part were organized in 1949 and 1950. A few states have assigned this function to already existing committees. Several associations reported such committees had been in existence for as long as fifteen and twenty years. It is apparent, however, that the Report of the Committee on Hospitals and the Practice of Medicine has resulted not only in the formation of many physician-hospital relations committees but also in increased activity on the part of long established committees.

Twenty-two of the state association committees reported activity during 1950. Among the matters with which these committees were concerned over the past year were: (1) physician-hospital relations; (2) revision of medical practice acts; (3) conferences with Blue Shield and Blue Cross; (4) recruiting of interns and residents; (5) training programs for hospital resident staffs; (6) studies of the costs of hospitalized illness; (7) studies of indigent medical care and (8) securing hospital licensure legislation.

Of the states reporting, only six had taken action in regard to the Report of the Committee on Hospitals and the Practice of Medicine as adopted by the House of Delegates, and all of these states had supported the Report. Four others indicated that the matter would be considered by their governing bodies.

The Committee on Indigent Care reports considerable progress in its study of the various types of programs through which medical care is provided to public assistance beneficiaries and to the borderline group often referred to as medically indigent. A study schedule has been completed with the cooperation and assistance of Professor Ira V. Hiscock, Chairman of the Department of Public Health, Yale University, and his staff.

The first study, to test the adequacy of the schedule and study method, is scheduled for completion late in May. On the basis of this experience, both schedule and method will be reviewed and revised as seem indicated. During the summer months studies will be made of a variety of indigent medical care plans in selected areas and the results will be reported to the House of Delegates in December. Primary emphasis is to be given to administrative organization and medical society relationship. Just how far the Committee can go in its suggestions and recommendations should become evident as the studies progress. There is no doubt but that at the present we are still at the fact finding stage.

It may also be well to report that the Committee has made arrangements to use the services of especially qualified temporary personnel to make the studies under the supervision of a regular Council staff member.

The Committee on Maternal and Child Care has been concerned primarily with liaison with interested groups and the medical problems of dependents of servicemen.

Two members of the Committee, Drs. W. L. Crawford and Donald A. Dukelow, were among the American Medical Association representatives attending the Midcentury White House Conference on Children and Youth held in Washington, D. C., December 3 to 7, 1950. During the White House Conference contact was made with Miss Katharine Lenroot, Director of the Children's Bureau of the Federal Security Agency. One of the conversations had to do with the present military situation and the possible medical care problems of the wives and families of servicemen. It was evident that some thinking was in process as to the necessity for looking forward to a reactivation of some plan similar to the E. M. I. C. program of World War II. It seemed evident, too, that the Children's Bureau would seek the advice and cooperation of the American Medical Association in any discussions on this matter.

With this in mind the Committee on Maternal and Child Care developed a short questionnaire which it sent to all state medical associations and approximately 400 physicians, including general practitioners, obstetricians and pediatricians. The purpose of the questionnaire was to learn how the state associations felt concerning the operation of E. M. I. C. and to get the reactions of physicians who had worked under the program. The survey was not intended to be exhaustive but merely to assist the Committee if and when it was called on to participate in discussions on the reactivation of E. M. I. C., and in this the survey has been most helpful.

An informal meeting of the Committee chairman and Association staff members with representatives of the Children's Bureau was held in Chicago on February 23. At that time a meeting of the full Committee with representatives of the Children's Bureau was arranged for March 10 in Chicago.

In order to prepare for the conference with the Children's Bureau representatives, the full Committee met in Chicago on Friday, March 9, to review the responses to the questionnaire. The following day, March 10, those present at the meeting with representatives of the Children's Bureau were: the Committee members, Drs. Crawford, Truman, Mengert, Mulholland and Dukelow; guests invited by the Committee, Drs. E. H. Christopherson, Clarence H. Webb and Philip S. Barba, members of the American Academy of Pediatrics, Dr. Philip F. Williams of the American Academy of Obstetrics and Gynecology and Dr. Garland D. Murphy Jr., a member of the American Legion Child Welfare Committee; staff members, Dr. George F. Lull, Mr. Thomas A. Hendricks and Mr. George W. Cooley.

Although no formal actions were taken at either of these meetings, nor was any representative asked to commit himself or his organization, the Committee believes that from a preliminary point of view it seems reasonable to draw the following conclusions:

1. No widespread emergency exists at this time which warrants setting up a special maternal and infant care program for wives and dependents of servicemen.

2. Requests or pressures for a nationwide re-enactment of such a program are few and far between and are usually based on individual instances arising near military installations where the influx of servicemen and families has resulted in abnormal conditions. Special consideration and planning will need to be given to these particular areas.

3. Where need occurs away from military posts, help for the individual needy case can usually be obtained through one or more of the numerous existing sources of aid, such as the Army, Navy and Air Force Relief Funds and the American Red Cross. The medical society should not be omitted as a source of assistance in the form of medical service, nor should the fact be ignored that many voluntary medical and hospital service plans are continuing to cover the families of servicemen on a special basis or as a continuation of benefits by employers.

4. Despite the fact that there is little indication of urgency in this matter, the unpleasant experiences with the E. M. I. C. program in World War II certainly indicate the value of planning ahead should a similar emergency occur.

5. It is evident from the replies to the questionnaire that the former E. M. I. C. program, while reasonably satisfactory in some areas and in some aspects, left much to be desired from the point of view of the veterans as well as the medical profession.

6. Any planning that is done should include consideration of the possibility of utilizing the voluntary health insurance plans and the state medical association agencies handling Home Town Veterans Medical Care Programs.

7. Any planning that is done should not be hastily assembled but should develop only as a result of serious consideration on the part of hospital authorities, state and Federal public health administrators, veterans representatives and the state medical associations representing the physicians who supply the medical service.

On the invitation of the Children's Bureau, the Committee chairman and secretary attended a conference held in Washington, D. C., April 4. Attending this meeting were representatives of the Advisory Committee for the Children's Bureau, the Blue Cross, American Academy of Pediatrics, Association of State and Territorial Health Officers, American Academy of Obstetrics and Gynecology, American Public Health Association, Catholic Hospital Association, Protestant Hospital Association and American Medical Association.

All discussions were informal and in no way committed the agencies represented to any statement or policy. It was generally accepted that no emergency regarding the dependents of servicemen exists at the present time, and, therefore, all of the discussions were of an exploratory nature. In other words, the group was merely thinking out loud as to the problems that would need to be considered if at some future date Congress believed there was an emergency in this matter and decided to consider legislation. It was generally agreed that any program that was put into effect should come as a result of legislation and not as a result of administrative action such as occurred during World War II. This, of course, would give all organizations an opportunity to be heard on the subject rather than wake up some morning to find a going operation established by administrative edict. Certainly discussion at this conference in no way altered the conclusions noted previously. In fact, if anything, it strengthened them.

The Council would like to point out that three organizations have requested the reactivation of some sort of a medical care program for the wives and children of servicemen. Mr. Walter Reuther has expressed the U. A. W.-C. I. O. desires through a letter addressed to Senator Lehman, a member of the Senate Labor and Public Welfare Subcommittee on Health. The American Legion passed a resolution at its national convention in October of 1950 urging the "establishment of an E. M. I. C. program similar to that operated during World War II, with due consideration given to correcting any inequities which the experience developed during World War II may have revealed." The Minnesota State Legislature has expressed its desires by memorializing Congress to enact such a program.

The Committee intends to follow developments on this matter. Particular attention will be given to a need for such a drastic step and, if necessary, it will conduct one or more studies in specific problem areas for the purpose of determining the extent of such need. The Committee has also before it a suggested study program covering both maternal care and child care.

The Committee on Federal Medical Services is being expanded, both in scope and in personnel, to comply with the recommendation of the House of Delegates. The Committee has held one meeting so far this year. As a result of that meeting, the Council has approved certain activities, which include the analysis of all aspects of the several forms of medical care financed under federal offices and the establishment of liaison with both nongovernmental and governmental agencies interested in federally financed medical care.

In the matter of increased Committee personnel, the Council has considered several persons. To date, Dr. Herbert P. Ramsey, Washington, D. C., and Dr. Joseph S. Lawrence, Director of the Washington Office, have consented to serve on the Committee, the latter in an ex officio capacity.

The Council contemplates the use of this Committee in an advisory capacity on all matters pertaining to federal medical services which do not involve the specific activities of other Council committees.

The Committee on Prepayment Hospital and Medical Service has met informally with representatives of the Health Insurance Council. The purpose of these informal meetings was to discuss some of the problems inherent to voluntary health insurance. In addition, these problems have been presented to the Blue Shield Commission. Although at this time neither the Health Insurance Council nor the Blue Shield Commission has submitted any definite plans for solving some of these problems, it is anticipated that some formal meetings and some formal recommendations will result in the relatively near future.

In the field of voluntary health insurance the Council has been involved in the study of Health Insurance Plans in the United States pursuant to Senate Resolution 273, 81st Congress, Second Session. This resolution authorized a special Subcommittee on Health of the Committee on Labor and Public Welfare of the United States Senate. Dr. Dean A. Clark, Director General of the Massachusetts General Hospital and formerly Medical Director of the Health Insurance Plan of Greater New York, was named as the Consulting Director of the Subcommittee on Health. Dr. Clark is also president of the Cooperative Health Federation of America.

Only one copy of a preliminary Confidential Committee Print was made available to the Council office. This may be due to the fact that only about 50 copies were printed. The print consists of 90 pages. While the statistical data appear accurate, the first and last chapters lack the objectivity stressed during preliminary conferences.

These chapters, entitled "Summary of Findings and Recommendations" and "The Role of Medical-Care Insurance," are written in a manner that implies the superiority of conducting health insurance programs through organized service units, such as hospitals and group medical practice, with payments to professional personnel on some basis other than fee-for-service. The Council authorized a statement to be sent to Dr. Clark. The principal purpose of the statement was to suggest changes which would make the report more objective and to confine the comments to the subject. This was a "Confidential Committee Print" and the Council has respected its status. As soon as the report is filed, and therefore no longer confidential, copies of pertinent portions of the report and also copies of the Council statement will be reproduced for the members of the House of Delegates.

While it will be some time before the Health Insurance Council has completed its Survey of Accident and Health Insurance in the United States for the year 1950, reliable estimates indicate that the number of Americans having some type of hospitalization insurance at the end of 1950 was 75 million and that some 52 million Americans were enjoying the benefits of voluntary surgical care insurance.

The Council is continuing its annual revision of Voluntary Prepayment Medical Care Plans started in 1946. The fifth annual (1951) revision is now available to the profession and other interested organizations and individuals.

The Supplementary Report of the Council at the 1950 Clinical Session indicated that medical society prepayment benefit plans had been developed in all forty-eight states, the District of Columbia and the Territory of Hawaii. During the year one local plan ceased to operate and its obligations were assumed by another local organization. This does not alter the fact that medical society plans exist in all states.

In an effort to determine the extent to which the voluntary health insurance plans made coverage available to dependents of military personnel, a special survey was undertaken. Of seventy-five returns, 67 plans continue coverage for dependents of military personnel and one plan is giving consideration to doing so. In most instances the coverage must have been in effect prior to the time the primary subscriber enters military service. Also, all 67 plans permit reinstatement of the coverage for the subscriber on his separation from military service. This normally requires a reinstatement application.

The Council's exhibit on Voluntary Health Insurance has been shown at five meetings since the last Annual Session. These were meetings of the Montana State Medical Association, the Indiana State Medical Association, the American Public Health Association, the American Academy of General Practice and the Illinois State Medical Society. This exhibit is being revised from time to time in the light of newer data and is currently being shown at booth 501 in the Scientific Exhibit.

The Committee on Relations with Lay Sponsored Voluntary Health Plans has held one meeting in Chicago subsequent to the meeting at the time of the Clinical Session in Cleveland. At that Clinical Session the House of Delegates approved a certain procedure for handling an application submitted on behalf of any lay sponsored voluntary health plan within the purview of the Twenty Principles.

One application is on file and the Committee on Relations with Lay Sponsored Voluntary Health Plans has been authorized to collect such data concerning the plan as it deems necessary before making recommendations to the Council. Since these additional data have not been supplied to the Committee, the Committee has been unable to make any recommendations to the Council and, consequently, the Council is not yet in a position to report definitely to the House.

Another problem before the Committee is the annotation of the Twenty Principles. The Council has accepted the recommendation of the Committee that annotation of the Twenty Principles should be withheld until such time as action has been taken on the pending application.

As additional information is supplied and as developments take place, they will be reported promptly by the Council to the House.

The Committee on Medical Care for Industrial Workers has concerned itself primarily, during the past four months, with a continuation of its study of temporary cash sickness benefits and the legislation enacted in California, Rhode Island, New Jersey and New York. Following through on the recommendation of the House of Delegates in December 1950, the Committee has completed a digest of the information that the Council staff has assembled. This is included in a Progress Report on Temporary Cash Sickness Benefits and Related Legislation, which has been sent, as suggested, to every member of the House of Delegates.

In response to requests from several state associations, the Committee prepared voluminous kits of material and sent them to these associations on a loan basis. As new material becomes available, it is added to these kits so as to keep them up to date.

Plans are under way for studies of a number of industrial and union programs providing medical care for industrial workers.

OTHER ACTIVITIES

The Physicians Placement Service continues to function effectively in cooperation with and as a supplement to the various state medical association placement services. For the most part the number of requests from communities seeking a physician is decreasing, and it would seem, at least compared to two or three years ago, that the distribution problem is slowly being met. This does not mean that there is an oversupply of physicians nor that there are yet enough physicians seeking locations to fill openings already available. It does mean, however, that at present the number of requests for openings during a given month is greater than the number of new requests for physicians during the same period.

The Placement Service has made particular effort during the past few months to obtain specific information as to what communities can and will do to attract a physician. It is interesting to note that in a majority of instances communities are making home or office facilities available, often either or both are rent free for a reasonable period of time. Undoubtedly, recent popular magazine articles describing what communities have done to attract physicians have had some effect on local attitudes. It may be too that the booklet which the Council sends to communities seeking physicians has had some effect in making these communities aware not only of their responsibilities but also of what can and is being done to attract able medical men.

Three projects are under discussion at the present time: one has to do with the American Medical Association establishing a revolving fund from which young physicians might borrow provided they agree to locate in certain strategic or critical areas; another has to do with several pilot studies designed to provide specific information and details concerning the steps that communities can take to attract physicians; and a third is concerned with a study of the financial needs of physicians at the time they finish their internships or residencies.

Distribution of Material: During the last three months of 1950 and the first four months of 1951 the Council distributed approximately 150,000 pieces of reference material in response to requests. In order to get material into school and public libraries without sending a very large and probably wasteful mailing, the Council has this year listed a number of key items with the Educators Progress Service and the H. W. Wilson Company. The Progress Service publishes the Educators Index of Free Materials for both elementary and secondary schools. The H. W. Wilson Company publishes the Vertical File Service Catalog for libraries. As a result of these listings, the number of requests from school and public libraries has increased tremendously.

Health insurance and socialized medicine continue to be the most popular and account for more than three-fourths of the requests. Of the loan kits on such subjects as group practice, health councils, cash sickness benefits and indigent care, the Group Practice Kit is most in demand.

Survey of County Medical Society Activities: The Council is continually called on for information concerning the organization and operation of activities carried on by county medical societies or in which county societies participate or cooperate with other groups. To keep up to date on these activities the Council has conducted a second general survey covering 757 county societies distributed throughout the forty-eight states. This is 502 more than the Council included in the first survey made in 1948 and, therefore, provides much more information than did the 1948 survey.

The 757 societies in the survey included 582 with less than 100 members (Group I); 72 with between 100 and 200 members (Group II); 37 between 200 and 300 members (Group III); and 65 with over 300 members (Group IV). The information obtained is tabulated according to these four groups so as to be of practical assistance to medical societies of all sizes. Total tabulation of some of the activities included in the survey shows that:

757 societies have regularly scheduled scientific programs;
263 societies sponsor postgraduate programs;
523 societies report library facilities are available to members;
545 societies participate in tuberculosis control programs;
503 societies participate in pre-school examinations;
448 societies participate in maintenance of blood banks;
533 societies participate in cancer control programs;
367 societies cooperate in a diabetes detection program;
149 societies cooperate in a rheumatic fever control program;
76 societies are experimenting with multiphasic screening;
364 societies have emergency call plans;
366 societies have grievance committees, and
296 societies have group accident and health insurance plans.

These, of course, are but a portion of the items. The complete story of the survey has been mimeographed for use by county medical society officers and is available to others on request.

Medical Service News Letter: The Council is seriously considering again publishing a monthly or quarterly news letter to apprise state and local committees of developments in the medical service field. A medium such as this is especially needed today, because many of the state medical associations and county societies have created committees paralleling the seven Council Committees. A news letter not only will bring about closer liaison between these committees at the various levels but will keep them continuously informed on such subjects as voluntary health insurance, cash sickness benefits legislation, and physician-hospital relations.

Staff Personnel: The Council has kept in mind the statement of the Chairman of the Board of Trustees last June and the recommendations of the Reference Committee on Insurance and Medical Service last December in regard to increasing its staff. On May 1 the Council employed Mr. Russell Staudacher as a staff assistant. Mr. Staudacher was formerly Associate Public Relations Counsel for the Michigan State Medical Society and in this capacity had considerable experience with the type of activities with which the Council is concerned. A number of other individuals have been considered, but because of the experience requirements, it is going to take time to augment the Council staff with qualified personnel.

SUPPLEMENTARY REPORT

Your attention is invited to the Report of the Council on Medical Service, especially to the program suggested by the Council, entitled "You and Your A. M. A."

Your attention is also invited to the comments on the Physicians Placement Service. A further report on this subject including a discussion of the feasibility of a revolving fund to assist physicians in locating in areas needing medical services has been presented to the Board of Trustees.

In addition to the above remarks concerning the Council's Report the attention of the members of the House of Delegates is invited to the attached "Supplemental Information on Temporary Disability Benefits."

In the report of the Council, mention is made of the fact that a "Progress Report on Temporary Cash Sickness Benefits and Related Legislation" has been sent to each member of the House of Delegates in keeping with the recommendation of the House in December 1950.

The Council at this time invites the attention of the delegates to two items of information received subsequent to the mailing of the report. In that report it is stated that "So far, in the four states which have such laws the medical profession and medical associations have given neither active support nor active opposition to the proposals." This referred to Rhode Island, California, New Jersey, and New York. The state medical association in each of these states was asked to comment on this statement within a specified time to permit mailing of the report prior to May 15. While no replies were received within the dateline set, since then the California Medical Association and Rhode Island Medical Society have replied in part as follows:

California

> The California Medical Association actively and vigorously opposed the establishment of the cash sickness disability law four years ago and the bill was passed through the legislature only after the insurance carriers who had sided with us had agreed to withdraw their opposition if they were permitted to participate in the underwriting program. That left the C. M. A. as the sole opponent to the measure and we weren't strong enough by ourselves to stop it.
>
> Two years ago we opposed the addition of hospital benefits to the original-bill. The hospital association joined with us in this opposition and we had the bill stymied until the few last days of the legislature, when a watered down bill was put through. This version removed many of our original objections and we found it impossible to stop its passage, especially since labor was crying for the application for its own purposes of funds contributed solely by employees.
>
> I think you should have that record on our opposition. On page 10 of your report you mention that business and insurance interests were opposed to the legislation but omitted our opposition. We have been and still are fearful that this type of legislation is the entering wedge for compulsory health insurance and that future amendments may be tacked on to increase the tax receipts and widen the services provided. As a matter of fact, the insurance carriers and labor unions this year agreed among themselves to approve an increase in the employees' tax rate to 1½% from 1% and to provide additional indemnities in the event of unemployment resulting from disability.

Rhode Island

> We are concerned with the first paragraph under the heading Group Five on page 8.
>
> A statement is made that "So far, in the four states which have such laws the medical profession and medical associations have given neither active support nor active opposition to the proposals."
>
> It is not clear to us what is meant by the word "proposals." We did not support or oppose the initial legislation. However, we have given active support to the program once it was established by the State of Rhode Island, and we have continued to seek to improve the program throughout the years. It was my belief that there was excellent cooperation in California, since the medical association was aware of our proposals and took an actve part in preparing the preliminary phases of the California Disability Plan once it had been enacted.
>
> Therefore, we would urge that the word "proposals" be clarified and also that mention be made, in so far as we are concerned, that the Rhode Island Medical Society has given active support to the state government in the carrying out of the medical phases of the Rhode Island Temporary Disability Insurance.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. William R. Brooksher, Chairman, presented the following report, which was duly adopted:

The progress report of the Council on Medical Service details the many fields in which the Council is at present engaged. Your committee is hopeful that the project "You and Your A .M. A." will receive hearty support from the constituent state associations. The continuing work of the respective subcommittees of the Council on Medical Service is commended.

The Council proposes to publish a newsletter on developments in the medical service field. Your committee received a resolution from the Ohio State Medical Association proposing regular dissemination of health insurance news in a publication of the American Medical Association. Your committee recommends that space be made available in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION which the Council on Medical Service may use for the regular presentation of medical service and health insurance activities.

Proposed Amendment to By-Laws

Dr. H. Russell Brown, South Dakota, presented the following proposed amendment to Chapter XIII, Section 1:

Amend Chapter XIII, Section 1, to read: Composition.—The Board of Trustees shall consist of nine elected Trustees, the President and President-Elect. The Vice President, Secretary, Treasurer, Speaker, Vice Speaker, General Manager and Editor of THE JOURNAL may attend meetings of the Board.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS

Dr. Robertson Ward, Chairman, presented the following report, which was duly adopted and the Speaker announced the By-Laws thus amended:

Referred to this committee was a resolution by Dr. Brown of South Dakota to amend the By-Laws in such fashion as to change the composition of the Board of Trustees by adding the President and the President-Elect. This same matter had been the subject of a study by the Interim Committee on Constitution and By-Laws on a similar resolution introduced by Dr. Brooksher of Arkansas at the last session of the House of Delegates. After a thorough discussion, participated in by Dr. McCarthy, the Chairman of the Interim Committee, this committee reached the conclusion that, in keeping with the practices of most large corporations and those of many of the constituent state medical associations, this was a desirable procedure. It therefore recommends the adoption of this change in the By-Laws, Chapter XIII, Section 1, so that it will read as follows:

> Section 1. Composition.—The Board of Trustees shall consist of nine elected trustees, as provided in Article 7 of the Constitution, the President and the President-Elect. The Vice President, the Secretary, the Treasurer, the Speaker, the Vice Speaker, the General Manager and the Editor of THE JOURNAL may attend meetings of the Board.

Resolution on Medical Supervision of Curative Workshops

Dr. Frank H. Krusen, Section on Physical Medicine and Rehabilitation, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Certain high-minded citizens have organized in various communities throughout the United States certain institutions known variously as curative workshops, institutes of rehabilitation, or rehabilitation centers in which both physical therapy and occupational therapy are employed in the treatment of sick and disabled persons; and

WHEREAS, Such curative workshops, institutes of rehabilitation or rehabilitation centers have in a number of instances failed to provide adequate direct medical supervision of the lay therapists who provide the physical therapy and occupational therapy; and

WHEREAS, Certain state medical societies have requested an explanation of the point of view of the American Medical Association concerning adequate medical supervision of such organizations; and

WHEREAS, The Council on Physical Medicine and Rehabilitation of the American Medical Association has expressed the opinion that all facilites which provide services in physical therapy and occupational therapy should be under the direct supervision of a properly qualified and duly licensed physician; therefore be it

Resolved, That the House of Delegates of the American Medical Association go on record as recommending that all curative workshops, institutes of rehabilitation, rehabilitation centers and other organizations of a similar nature which provide services in physical therapy and occupational therapy shall conduct such medical treatment under the direct supervision of a properly qualified and licensed physician.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

Your reference committee approves of this resolution.

Resolutions on Lay Advertising

Dr. R. J. Azzari, for the Medical Society of the State of New York, submitted the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Certain advertising material is being distributed in various parts of the United States; and

WHEREAS, This advertising extols the choice of a specialist in obstetrics and a specialist in pediatrics as compared with the choice of a general practitioner for the care of maternity and pediatric patients; and

WHEREAS, Said advertising extols hospitals approved by the American College of Surgeons as compared with others that may not be so approved; and

WHEREAS, Certain advice regarding sexual intercourse, certain comments on premature delivery, certain illustrations of vertex and breech presentations are contained in these publications; therefore be it

Resolved, That the House of Delegates of the American Medical Association deprecates the spirit and inferences contained in such advertising matter, the unjust discrimination against general practitioners, those who have educated them, and the governmental bodies which have licensed them; and be it further

Resolved, That the Board of Trustees of the American Medical Association request the Better Business Bureaus, the United States Chamber of Commerce, or any other appropriate body, to use its influence toward accomplishing the cessation of such biased advertising.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented a report, which, including the following substitute resolution, was duly adopted:

WHEREAS, A large amount of advertising by pharmaceutical houses and other business and promotional programs, including those selling maternal and layette supplies, has in many instances been objectionable and not in the best interest of the public; and

WHEREAS, Certain statements concerning medical practice are inaccurately presented and appeal in varying instances to the public, by-passing the medical profession and disregarding established standards; therefore be it

Resolved, That the House of Delegates recommends to advertising agencies that they make all efforts possible to correlate their advertising programs with the principles of the best practice of modern medicine.

Your Reference Committee recommends that this substitute resolution be adopted instead of the Resolution on Lay Advertising and Resolution on Sales Promotion Methods of Pharmaceutical Houses.

Resolution on Restricted Membership

Dr. Andrew A. Eggston, New York, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Resolved, That the House of Delegates of the American Medical Association request the Secretary and the officers to collect, organize and make available to interested constituent state associations and component county societies, for their guidance and assistance, all pertinent information and experiences bearing on possible restrictions to membership based on race or religion.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

As this question is being considered in the communities involved and progress has been made, and since membership should be considered on a local, not a national level, your reference committee disapproves of this resolution.

Resolution on Approval of Program for Promotion of Research, Education and Preventive Service

Dr. William L. Benedict, Section on Ophthalmology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, It is estimated that 260,000 Americans are blind and many hundreds of thousands more are severely visually handicapped; and

WHEREAS, Much of this blindness could be prevented by research to improve methods of diagnosis, treatment and prevention, by education of the public and other groups and by promoting the provision of such preventive services as vision-testing of children, industrial eye programs and social service follow-up; and

WHEREAS, The National Society for the Prevention of Blindness was organized in 1908 to unite lay and professional forces in an all-out attack against unnecessary blindness and has carried on its program over the years, working closely with the medical profession and all interested groups; therefore be it

Resolved, That the American Medical Association approve the program of the National Society for the Prevention of Blindness for the promotion of research, education and preventive service.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

Your reference committee approves this resolution.

Resolution on Costs of All Technical and Professional Training

Dr. E. F. Hoffman, California, submitted the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, It is good accounting practice for business organizations to establish the costs required to create the going concern and to depreciate this capital initial cost over an appropriate period; and

WHEREAS, This procedure has met with the approval of the Department of Internal Revenue and is customary; and

WHEREAS, The costs of a professional education are dispersed over a period of years during which there is no income to offset these costs; and

WHEREAS, These costs represent a capitalization charge which thus constitutes a taxable loss to the individual; and

WHEREAS, All occupational training expenses are now neglected in this fashion; now, therefore, be it

Resolved, That the American Medical Association seek appropriate legislation to authorize the establishment, for tax purposes, of the costs of all technical and professional training to be amortized over an appropriate period.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, presented the following report, which was duly adopted:

After thoughtful deliberation, your committee believes that the problems involved in this resolution are so complex that action should be deferred until the matter has received consideration by the Board of Trustees. Your committee recommends, therefore, that this resolution be referred to the Board of Trustees.

Resolution on Investigation of School System

Dr. E. F. Hoffman, California, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, The American Medical Association, its constituent state associations and the component county associations thereof are now and have been for some time engaged in a bitter and grueling struggle to prevent the socialization of medicine with its inevitable accompaniment of the ultimate disintegration and destruction of good scientific care; and

Whereas, The socialization of medicine is just one phase of a long-range plan to collectivize every phase of our economic and social structure; and

Whereas, Many of our educators and many of the organizations to which they belong have for many years conducted an active, aggressive campaign to indoctrinate their students in grammar school, high school and college with the insidious and destructive tenets of the welfare state, beginning with John Dewey and the philosophy of progressive education as promulgated by the Columbia University Teachers College, this teaching of hatred and scorn for the American system of private enterprise having been so widespread and successful that as a result our voters are conditioned to accept all manner of totalitarian expedients in direct violation of economic law; and

Whereas, The Sons of the American Revolution presented to the last Congress a Bill of Grievances, setting forth specific instances of such teachings by individuals and the subversive textbooks to implement such teachings, and calling for a Congressional investigation of such teachings to the end that proper remedial steps might be taken; now therefore be it

Resolved, That the American Medical Association be requested to call on Congress to make a thorough investigation of our entire school system with particular reference to the teachers and authors of text-books advocating the overthrow of the American system of free enterprise by the infiltration of the un-American fallacies of collectivism.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, presented the following report, which was duly adopted:

The resolution introduced by Dr. E. F. Hoffman, California, has been amended with the approval of Dr. Hoffman and now reads as follows:

Whereas, The American Medical Association, its constituent state associations and the component county associations thereof are now and have been for some time engaged in a bitter and grueling struggle to prevent the socialization of medicine with its inevitable accompaniment of the ultimate disintegration and destruction of good scientific care; and

Whereas, The socialization of medicine is just one phase of a long-range plan to collectivize every phase of our economc and social structure; and

Whereas, Many of our educators and many of the organizations to which they belong have for many years conducted an active, aggressive campaign to indoctrinate their students in grammar school, high school and college with the insidious and destructive tenets of the welfare state, this teaching of hatred and scorn for the American system of private enterprise having been so widespread and successful that as a result our voters are conditioned to accept all manner of totalitarian expedients in direct violation of economic law; and

Whereas, The Sons of the American Revolution presented to the last Congress a Bill of Grievances, setting forth specific instances of such teachings by individuals and the subversive textbooks to implement such teachings, and calling for a Congressional investigation of such teachings to the end that proper remedial steps may be taken; therefore be it

Resolved, That the American Medical Association endorse the principle of requesting the Congress to make a thorough investigation of our entire school system, with particular reference to the teachers and authors of textbooks advocating the overthrow of the American system of free enterprise by the infiltration of un-American fallacies of collectivism; and be it further

Resolved, That a copy of this resolution be sent to the President, the Vice President and members of the United States Senate and the House of Representatives.

Resolution on Pension Plans and Profit Sharing Trusts

Dr. William D. Stovall, Wisconsin, submitted the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, The Internal Revenue Code provides for special treatment in the case of pension plans and profit sharing trusts adopted by employers for the benefit of employees to the extent that the contributions of the employer to the pension plan, or profit sharing trust, are deductible by the employer as expense for Federal income tax purposes, and to the further extent that the benefits accruing to the employee under the pension plan, or profit sharing trust, do not constitute taxable income to said employee until he receives actual distribution from the pension plan, or profit sharing trust, at which time the actual distributions are taxable income; and

Whereas, Such aforementioned provisions with respect to pension plans and profit sharing trusts permit employees and officers of corporations who are in high personal income tax brackets actually to receive a portion of their compensation in the form of pension plan benefits, or profit sharing trust benefits, without the payment of personal income tax thereon at the time the benefit is provided by the employer; and

Whereas, Such procedure permits employees in high income tax brackets to provide for retirement which would be impossible were they to attempt personally to provide for retirement out of income remaining after payment of Federal personal income taxes at high rates; and

Whereas, The Federal income tax law in the case of profit sharing trusts permits the annual benefit provided for employees of corporations to attain a level of 15 per cent of the compensation otherwise received; and

Whereas, These pension plan and profit sharing benefits are not available to self-employed business and professional men, whether partners or sole proprietors, and there is no reason for such arbitrary discrimination; now, therefore, be it

Resolved, That this Association does recommend that the Congress of the United States amend the Federal Income Tax Code to provide—

(*a*) All self-employed business and professional men, including partners and sole proprietors, be permitted to set aside for purposes of retirement up to, but not exceeding, fifteen per cent of their annual income each year under a set plan and formula filed with the Bureau of Internal Revenue, said amount so set aside to be a deduction for Federal income tax purposes.

(*b*) On the self-employed individual drawing on the amount so set aside in accordance with the provisions of the plan provided, the amount so drawn becomes taxable income to him, or to his heirs, even as is now provided with respect to benefits actually paid to employees out of pension plans and profit sharing trusts under the Internal Revenue Code.

Resolution on Pension Plans By Corporations

Dr. W. H. Huron, Michigan, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, Present laws allow pension plans by corporations for both executive and labor groups; and

Whereas, The earning power of professional people is crowded into a relatively short span of years which places them in a higher income bracket during that time with little opportunity under present high income taxes to create a pension for themselves; therefore be it

Resolved, That the American Medical Association seek to remove present discrimination against professional people in matters of income tax levies by joining with the American Bar Association and other professional groups to initiate legislation in Congress which will amend the existing pension trust provisions so as to permit partners and individual proprietors to formulate pension plans, the costs of which are deductible in computing income tax, but to be subject to taxation when the trust is effective.

Resolutions on Retirement Benefits for Professional Persons

Dr. W. P. Anderton, New York, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, The present high levels of federal taxation on earned income make it virtually impossible for professional persons and other recipients of earned income to provide from this income for retirement; and

Whereas, The problem of providing retirement benefits has to a great extent been solved for corporate employees by Section 165 of the U. S. Internal Revenue Code; and

Whereas, The need for such retirement benefits is equally great in the case of professional persons and other persons having earned income but not covered by a pension plan; and

Whereas, The American Bar Association has made a special study and has prepared legislation to be submitted to Congress aimed at making available retirement benefits for those persons having earned income but not covered by a pension plan; therefore be it

Resolved, That the House of Delegates of the American Medical Association urge the Board of Trustees to support and seek to participate in all measures that may facilitate the enactment of such legislation into law; and be it further

Resolved, That this House of Delegates approve in principle United States House of Representatives Bill No. 3456, introduced by Mr. Frederic R. Coudert, Jr., 17th District, New York.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, submitted the following report, which was duly adopted:

Your reference committee has given careful consideration to the three resolutions referred to it relating to pension plans for physicians, introduced by Dr. Huron of Michigan, Dr. Anderton of New York and Dr. Stovall of Wisconsin. Since all of these resolutions deal with the same subject matter, they were considered jointly.

The objective sought is to establish a procedure whereby physicians and members of other professional groups may during their most productive years provide for their old age and less productive years by the purchase of retirement benefits with tax deferred income, the benefits being taxable when received. Such a procedure is presently available for the benefit of employees and officers of corporations but not to taxpayers who are self-employed.

The Board of Trustees in February, 1948, gave consideration to a somewhat similar proposal and approved it in principle. At a subsequent meeting of the House of Delegates, also in 1948, the action of the Board was expressly commended by the House. Since that time the directors of the Bureau of Medical Economic Research and of the Bureau of Legal Medicine and Legislation have had a number of conferences with representatives of the American Bar Association and of the Association of the Bar of New York City in an effort to develop appropriate legislation for presentation to Congress. Your Reference Committee has been informed that the draft of legislation being prepared by a special committee of the American Bar Association is approaching final form which will be introduced in the Congress in the near future.

There have been introduced in the Congress from time to time a number of bills dealing with this subject. There are now pending the bill referred to in the New York resolution, H. R. 3456 and another introduced within the last several days. Your reference committee does not believe it timely for the House to express its support of any particular bill. It does recommend that the House re-emphasize its 1948 endorsement of the principle embodied in this proposal, with a reasonable ceiling on the amount of the retirement benefit and that the Board of Trustees be requested to continue its efforts in support of this principle, giving special consideration to any legislation formulated by the American Bar Association.

Resolution on Appointments to the Commission on Accreditation of Hospitals

Dr. C. A. Nafe, Indiana, presented the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, There has been a tendency on the part of some hospitals in some parts of the United States to limit staff membership and deny to general practitioners the facilities of those hospitals; and

WHEREAS, There is no specific provision in the establishment of the Joint Commission on Accreditation of Hospitals for representation of the general practitioner, while there is for the surgeon and internist; and

WHEREAS, It is to the best interest of the medical profession and of the public generally to maintain proper hospital facilities for general practitioners to care for the patients; therefore be it

Resolved, That this House of Delegates request that an adequate number of general practitioners be appointed at all times to the Joint Commission on Accreditation of Hospitals.

(For report of Reference Committee on Medical Education and Hospitals, see its report under Report of Board of Trustees.)

Resolutions on Hospital Standardization

Dr. Ralph A. Johnson, Michigan, presented the following resolutions, which were referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The American Medical Association has long conducted the inspection of hospitals with reference to their desirability for intern and resident training; be it

Resolved, That this House of Delegates believes that the American Medical Association should extend that inspection service to include the inspection of all portions of hospital care and looking to the standardization of hospitals; and be it further

Resolved, That the Board of Trustees be and is hereby directed to implement this policy and to proceed to the general inspection of hospitals inviting the cooperation of any other national organizations which have an interest in this problem.

(For report of Reference Committee on Medical Education and Hospitals, see its report under Report of Board of Trustees.)

Resolution on Preceptorship for Medical Students

Dr. R. Stanley Kneeshaw, California, presented the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The training of the medical student today in the science of medicine is of the highest caliber, but that training does not include instruction in the art of practice or in the basic economics so essential in modern society; and

WHEREAS, This essential fundamental training could well be provided by a system of preceptorship in which the student would be placed under the guidance of a successful practitioner in his locality, such allocation to be made by the county medical society with the aid of registration facilities provided by the Student American Medical Association; now therefore be it

Resolved, That the Board of Trustees be requested to establish a system of preceptorship for the instruction of medical students in the art and economics of the practice of medicine, such a system to be organized within the framework of the Student American Medical Association and with the aid and approval of the local county society.

Report of Reference Committee on Medical Education and Hospitals

Dr. William Bates, Chairman, presented the following report, which was duly adopted:

Your committee is in complete sympathy with the intent of this resolution. It should be pointed out that already fourteen medical schools have adopted the preceptorship idea. The committee recommends that at the national level the Council on Medical Education and Hospitals continue its study of preceptorships, and that it invite representatives of the Student American Medical Association to sit in at its meetings. Details of the system of preceptorships must necessarily vary in different communities and your committee recommends that such details be left to the individual deans' committees of medical schools, the local chapter of the Student American Medical Association and the local county and/or state medical society.

Resolution on National Education Fund

Dr. Leo F. Schiff, for the Medical Society of the State of New York, submitted the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The American Medical Association is actively engaged in a campaign to raise funds for the maintenance of medical education without governmental support and control; and

WHEREAS, All physicians regardless of their school of graduation are being asked to contribute annually to this fund; and

WHEREAS, Such contributions by individual doctors will tend to discourage contributions by them to schools of their choice as alumni of such schools; and

WHEREAS, Many schools depend to a great extent on their alumni for continued financial support; and

WHEREAS, Such alumni support varies widely in different schools both as to percentage of contributing alumni and sums contributed; therefore be it

Resolved, That the House of Delegates of the American Medical Association urge the American Medical Education Foundation to accept contributions in such manner as to permit the allocation of all or any part of a contribution to a particular medical school at the request of the contributor.

Report of Reference Committee on Medical Education and Hospitals

Dr. William Bates, Chairman, submitted the following report, which was duly adopted:

As the Chairman of the American Medical Education Foundation has already announced to this House that the purpose of this resolution, the allocation of all or any part of any individual's contribution to a particular medical school at the request of the contributor, has already been arranged for and plans made for implementing it, your Committee approves of the action taken by the American Medical Education Foundation and commends the Medical Society of the State of New York for its constructive thinking as demonstrated by its resolution.

Resolutions on Blue Shield

Dr. R. L. Novy, Michigan, presented the following resolutions, which were referred to the Reference Committee on Insurance and Medical Service:

WHEREAS, Certain organized medical societies throughout the country have caused to be created seventy-four (74) nonprofit voluntary prepayment plans known collectively as the Blue Shield plans to meet the costs of medical care for major or serious illnesses; and

WHEREAS, This Blue Shield movement has met with widespread public approval now covering over 20 million people, having grown in size 35 per cent in the past year; and

WHEREAS, Over 100,000 practicing physicians are participating physicians in these plans; and

WHEREAS, Over 725 practicing physicians on the various governing boards of the Blue Shield plans are giving their time and counsel to direct and further increase the usefulness of these plans in the public interest; and

WHEREAS, In this House of Delegates of the American Medical Association nearly one-third of the members are serving not only organized medicine but also serving in official policy-shaping capacity for the Blue Shield plans; therefore be it

Resolved, That the House of Delegates of the American Medical Association in annual session assembled does hereby express its appreciation and extend its congratulations to the several sponsoring medical societies for the constructive, positive program known as the Blue Shield plans that they have so admirably and wisely initiated and continue to develop in the public interest; and be it further

Resolved, That this House of Delegates expresses itself as cognizant of the responsibility these societies have unselfishly assumed in administering a great public trust in behalf of the medical profession and for the benefit of the American people.

Report of Reference Committee on Insurance and Medical Service

Dr. William R. Brooksher, Chairman, submitted the following report, which was duly adopted:

Your committee recommends approval of this resolution with amendments to provide that approval, commendation and congratulations be extended not only to the medical societies sponsoring Blue Shield Medical Care Plans but to those medical societies that sponsor other plans for the provision of the cost of medical care for major and serious illnesses.

Resolution on Insurance Reporting Forms

Dr. R. L. Novy, Michigan, submitted the following resolution, which was finally referred to the Reference Committee on Miscellaneous Business:

Whereas, In many cases insurance reporting forms of commercial insurance companies are unduly long, require excessive duplication and thus make completion of these forms unnecessarily time consuming; and

Whereas, Difficulty lies in obtaining cooperation towards shortening these forms by any state medical society due to the national character of the insurance companies; and

Whereas, For any state to adopt a uniform reporting form would be unsatisfactory to insurance companies; and

Whereas, This problem is not unique to Michigan doctors but is common to all members of the medical profession; therefore be it

Resolved, That the American Medical Association consider this problem and in collaboration with insurance companies of America develop mutually satisfactory reporting forms of a more efficient and shortened variety.

Report of Reference Committee on Miscellaneous Business

Dr. Andrew A. Eggston, Chairman, submitted the following report, which was duly adopted:

Your reference committee invites your attention to the fact that certain simplified forms have already been approved by the Council on Medical Service. This information appears not to be generally known and the Council on Medical Service is requested to supply each constituent medical association with copies of these simplified forms.

Your reference committee, with the above comments, approves of this resolution.

Resolution on Medical Prepayment Plans

Dr. H. P. Ramsey, District of Columbia, submitted the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

Whereas, The growth of medical prepayment plans sponsored by medical societies is a source of great satisfaction; and

Whereas, The growth has revealed the strength and weaknesses of these plans; and

Whereas, Critical years are ahead for medical prepayment plans and the sympathetic understanding and cooperation of all physicians is essential; and

Whereas, It is vitally important that the best possible relationship should exist between the American Medical Association and the plans sponsored by medical societies; therefore be it

Resolved, That the House of Delegates authorize the creation of a special committee to study the relationships between the American Medical Association and medical society-sponsored prepayment plans, and that it submit its findings to the House at the Interim Session in Los Angeles.

Report of Reference Committee on Insurance and Medical Service

Dr. William R. Brooksher, Chairman, presented the following report, which was laid on the table:

Your reference committee believes that such a study should be conducted by the already established Council on Medical Service of the American Medical Association and recommends that it be directed to conduct the proposed study and to report its findings at the Clinical Session in Los Angeles.

Resolution on Distribution of Medical Care

Dr. William F. Costello, New Jersey, presented the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

Whereas, The Twelve Point Program of the American Medical Association for the Advancement of Medicine and Public Health contains the following recommendation, in Point Number 3, relating to voluntary insurance:

"Further development and wider coverage by voluntary hospital and medical care plans to meet the costs of illness, with extension as rapidly as possible into rural areas. Aid through the states to the indigent and medically indigent by the utilization of voluntary hospital and medical care plans with local administration and local determination of needs"; and

Whereas, *The American Medical Association has steadfastly maintained* that the problem of assuring adequate medical care to all the people can be solved without resort to any national legislation that would establish a governmental monopoly in the provision of medical service or impose governmental dictation and control over the practice of medicine; and

Whereas, The American Medical Association believes that, as a matter of sound public policy, all agencies of government should stimulate and encourage the voluntary cooperative agencies created by the people to solve their social problems, never supplanting or superseding such agencies; and

Whereas, The American Medical Association recognizes an obligation to translate *into action its declared purposes concerning the* "further development," "wider coverage," and "extension" of voluntary hospital and medical care plans; *therefore be it*

Resolved, By the House of Delegates of the American Medical Association, in annual meeting assembled in Atlantic City this 11th day of June, 1951, that the following statement and proposals be approved and promulgated as the official action program of the American Medical Association.

PREAMBLE

The American Medical Association favors, and always has favored, a constructive approach to the solution of the national health problem. The solution of medical and health problems should be undertaken in a realistic, scientific spirit. Moreover, since the health of the people transcends all political considerations, it must be considered on a nonpartisan basis.

The American Medical Association believes there are areas in which government may beneficially cooperate with the citizens, individually or acting through voluntary assocations, in furthering a health program in the interest of all the people, and without jeopardy to individual liberty. It is generally recognized that voluntary cooperative effort should have priority at all times. Government should seek to promote and supplement the efforts of free citizens (not to supplant or supersede voluntary action), whenever voluntary cooperative effort can meet the need.

Any constructive approach to solution of the health problem must take into account the several classifications of those who require medical care, namely, (1) those who are able to sustain the full cost of providing for hospital and medical care, (2) those who are employed for wages and salaries in the medium income brackets, (3) the "medically indigent," whose income does not suffice to meet the costs of catastrophic illnesses, (4) the totally indigent, who are on public assistance rolls, and (5) the chronically ill.

Any adequate program to meet health needs should include medical and hospital care. Insofar as possible, such care should be so inclusive that everyone may budget in advance against the financial burden of sudden illness. In addition, the program should assure every community of basic health protection through well-organized professional public health departments.

No matter what program is devised, it should be experimental, flexible and evolutionary in character. It should be sufficiently concrete as to be readily understood and practically adaptable everywhere.

The American Medical Association, therefore, offers the following proposals for a cooperative health program, in which national, state and local governments may participate, without endangering individual initiative, personal freedom or scientific progress. The sequence in which this program is set forth does not necessarily indicate the relative importance of its parts.

PROGRAM

1. Voluntary nonprofit organizations should be used as the best means of budgeting hospital and medical service for the individual and his family.

(*a*) The Blue Cross movement, providing for hospital care on a nonprofit, minimum cost basis, is recognized as the outstanding development in this direction. Blue Cross has extended to nearly every part of the United States. There are now 96 Blue Cross organizations with a combined enrolment of more than 35 million people.

(*b*) The Blue Shield movement, launched within the past decade, has made possible the prepayment of medical care on a budget basis, which in some areas means that the doctor's bill for eligible care is covered in full for 80% of subscribers and their dependents, of whom there are now more than 12 million persons enrolled throughout the United States.

2. For persons able and willing, at their own expense, to meet the cost of enrolment in such voluntary nonprofit organizations, we propose that the premiums be made eligible for deduction for income tax purposes, regardless of the financial status of the subscriber or the amount of the premium paid.

Such deduction is equitable, inasmuch as employers who pay or contribute to the enrolment cost for their employees are already permitted to deduct these costs for income tax purposes, in cases where the latter enters into the computation of Federal income tax.

3. For employed groups, it is encouraging to note the growing practice of the employer contributing toward the cost of health and welfare programs for his employees and dependents. As mentioned, such payments are usually tax-deductible as part of the cost of production, and are being increasingly recognized as a legitimate part of that cost.

4. As an immediate encouragement toward employer contribution toward the enrolment cost of hospital and medical protection, government, at every level from municipal to national, should promote the program of such protection for its own employees by assuming either a part or all of the cost of enrolment in voluntary prepayment plans.

5. As rapidly as possible, consistent with actuarial experience and sound administration, the services eligible under such voluntary nonprofit organizations should be extended to cover all nonchronic ailments on an inclusive basis.

6. After sufficient enrolment is attained, we recommend that consideration be given the practicability of providing medical care protection on an inclusive basis to subscribers in voluntary, nonprofit plans, regardless of the financial status of the subscribers, and with no salary limitation for over-all inclusive service.

7. We propose that immediate study be given the possibility of providing voluntary, nonprofit protection for those who are "medically indigent" though not on public assistance rolls, through the use of state and local funds for the purchase of such protection. As a rule of thumb to determine "medical indigency," the criterion might be the question whether one's taxable income is such as to exempt him from payment of Federal income taxes.

8. For the medical and hospital care of persons on public assistance rolls, we recommend the providing of service through state-county-municipal funds, perhaps utilizing on a cost basis the voluntary nonprofit organizations for the actual provision of the required services.

9. There is no actuarially sound basis yet established for treating the chronically ill as an insured group. We suggest, therefore, that study be given to providing care for needy persons suffering from chronic illness, on a cost basis at state level, again with the possibility of utilizing the facilities of voluntary nonprofit organizations.

10. The need for better local public health service in most areas of the United States has long been recognized, but progress in providing it has been discouragingly slow. We recommend that every state government adopt such legislation as may be needed to permit consolidation of local health jurisdiction into districts having sufficient size and resources to support at least a minimum staff and facilities for complete modern basic public health protection.

11. There are numerous areas in certain states where the private practice of medicine is economically or professionally impractical, because the areas will not sustain a sufficient number of capable physicians on a fee-for-service basis, or because hospital facilities are inadequate or lacking. Progress is being made under the Hill-Burton Hospital Survey and Construction Act toward meeting the deficit of hospital accommodations. We suggest exploring the possibility of the U. S. Public Health Service providing competent physicians to such areas when requested by state or local agencies.

12. Such a cooperative health program as is here envisaged may require a considerable increase in the number of physicians, health officers, nurses and other medical personnel. Ideally, every qualified person desiring to enter the field of medicine and public health should be able to do so. We support a program of government subsidy, where needed, to assist qualified individuals in obtaining professional training and to expand professional training facilities where it is found possible to expand existing schools or to establish new ones. We believe that any governmental subsidy that may be provided for these purposes should be granted unconditionally to approved institutions.

The American Medical Association submits that through such voluntary cooperative action, the problem of attaining an adequate national health program can and will be solved.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. William R. Brooksher, Chairman, submitted the following report, which was duly adopted:

The Medical Society of New Jersey's resolution offering proposals for a cooperative health program in which national and state governments may participate was ably presented. Your committee is advised of the action of the House of Delegates this morning in approving that portion of the report of the Reference Committee on Reports of Board of Trustees and Secretary which recommends that the special committee authorized by the House of Delegates at the 1950 Annual Session in San Francisco be empowered to formulate a statement of policy that will guide the Association and its constituent societies in implementing the Twelve Point Program. Your committee recommends that this special committee give full and sympathetic consideration to the proposals submitted in this resolution with a view toward immediate adoption of some, and that it give study to the applicability for subsequent adoption of the remaining proposals.

Resolution on Exchange Students

Dr. W. F. Costello, New Jersey, presented the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The United States of America is proclaiming the philosophy of the Brotherhood of Man and is prosecuting a policy of education in its efforts to secure world peace; and

WHEREAS, The art and science of medicine knows no national boundaries; therefore be it

Resolved, That the Medical Society of New Jersey approves the principle of exchange students in the interest of better understanding between men and approves of hospitals in this state accepting for intern training citizens of foreign countries who are recent graduates of acceptable foreign schools, and that the medical staffs of said hospitals be urged to teach not only the best in American medicine but also, by example and precept, the best in American democracy, with the hope that the exchange student will be so saturated with democracy as to be effective in sowing the seeds of democratic principles on his return home.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, submitted the following report, which was duly adopted:

Your committee feels that the principles involved are worthy of wider adoption and hereby recommends that this House of Delegates publicize this activity of the Medical Society of New Jersey to all component societies so that all states where laws and regulations of those bodies having charge of intern training permit may utilize this plan of education and grass roots indoctrination in the fundamentals of democracy.

Resolutions on Proposing Greater Federal Economy

Dr. William R. Brooksher, Arkansas, submitted the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, Economy in government presupposes a wise expenditure of funds which have been exacted from the people by taxation; and

WHEREAS, It is desirable that a halt be put to the indiscriminate granting of federal subsidies for purposes which are amply able to pay their own way; and

WHEREAS, A beginning in such a reform should be immediately inaugurated, to commence not with others but with the advocates of such a reform; and

WHEREAS, The postgraduate courses provided from tax funds by the Federal Government are highly instructive and beneficial to the medical profession but can be financed without difficulty by those who are the recipients of such educational services, and it is the desire of the medical profession of Arkansas to pay personally such fees for the postgraduate instruction as is received in the future; now therefore be it

Resolved, By the House of Delegates of the Arkansas Medical Society that our Congressional delegation be and is hereby requested to make such efforts as may be necessary to eliminate from future budgets the expense of conducting courses of postgraduate work for the medical profession; and be it further

Resolved, That our delegates to the American Medical Association be instructed to present this resolution to the House of Delegates of the American Medical Association in annual session at Atlantic City, June 11-15, 1951.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, reported that the reference committee approved the resolutions and recommended their adoption and this report was duly adopted.

Resolutions on Professional Standards in Hospitals to be Vested in American Medical Association

Dr. Karl S. J. Hohlen, Nebraska, submitted the following resolutions, which were referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The American College of Surgeons has announced its decision to discontinue the program of hospital standardization it has so ably conducted for many years; and

Whereas, The American Hospital Association Board of Trustees subsequently announced that the American Hospital Association would "assume full responsibility for the hospital standardization program now conducted by the American College of Surgeons," and its House of Delegates increased association dues to finance the program; and

Whereas, Objections raised by the American Medical Association, the American Academy of General Practice and others to control of hospital medical practice by the American Hospital Association led to a series of conferences between representatives of the American Medical Association, the American Hospital Association, and the American College of Surgeons; and

Whereas, A compromise agreement has now been proposed for the creation of a joint committee composed of representatives from the American Medical Association, the American Hospital Association, the American College of Surgeons and the American College of Physicians, said committee to have complete authority over the evaluation and standardization of hospitals, including both administrative and professional aspects; and

Whereas, The evaluation and standardization of medical practice in hospitals is of such paramount importance to all branches of the medical profession that it should be under the sole and complete authority of the American Medical Association, which is the only medical organization representative of the entire profession in America and in which all segments of the profession have official democratic means for expressing their views on matters of such importance as the control of hospital medical practice; and

Whereas, The creation of an extramural committee with authority over this important aspect of modern medical practice would deny those branches of the profession not officially represented on such committee an official voice in the establishment and control of policies and procedures; now therefore be it

Resolved, That, regardless of what other organizations may undertake in connection with the standardization of nonprofessional matters in hospitals, the sole responsibility for the evaluation, standardization and control of medical practice in hospitals should be vested in the Council on Medical Education and Hospitals of the American Medical Association; and be it further

Resolved, That a copy of this resolution be furnished each Nebraska delegate to the American Medical Association with instructions that it be presented to the House of Delegates of the American Medical Association at its annual meeting in June 1951.

(The report of the Reference Committee on Medical Education and Hospitals may be found under the Report of the Board of Trustees.)

Resolutions on Combining Staff Meetings with County Medical Society Meetings

Whereas, The attendance at required hospital staff meetings has become a burdensome responsibility in communities wherein there is more than one hospital; and

Whereas, Attendance and interest in the county medical society is suffering by reason of the above; and

Whereas, The county medical society is the important unit in the solidarity of the physicians of city, county, state and nation; therefore be it

Resolved, That the Lancaster County Medical Society instruct its delegates to present this resolution to the House of Delegates of the Nebraska State Medical Association at its next session; and be it further

Resolved, That the said House of Delegates instruct the Nebraska delegates to the American Medical Association to present a resolution to the House of Delegates of the American Medical Association asking that the officers and other proper officials take cognizance of the increasing number of hospital staff meetings that require attendance of the staff in order to preserve staff membership and hospital rating, and that it be pointed out to the said officers and officials that the activities and interests of the county medical society, both scientific and organizational, must at all times be paramount to those of hospital staffs; and be it further

Resolved, That the delegates to the American Medical Association incorporate in their resolutions a request that the rules and regulations pertaining to hospital staff meetings be so modified as to permit the combining of staff meetings and clinical pathological conferences with county medical society meetings where such combinations are the desire of the membership.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, presented the following report, which was duly adopted:

Your committee realizes the time consuming demands made by required attendance at multiple medical meetings, as well as the requirements of attendance at hospital staff meetings by the Council on Medical Education and Hospitals of the American Medical Association, and the more stringent requirements in like respect to maintain good standing regarding staff appointments by the American College of Surgeons, as well as the high desirability of attendance at meetings of the local county medical societies. In order that the American Medical Association reopen a consideration of this problem before discussed by this House, your committee recommends that the Council on Medical Education and Hospitals study the whole problem of multiplicity of medical meetings and report its findings in this respect, perhaps after consultation with the American College of Surgeons, back to this House in December, paying particular attention to the desirability of setting up the mechanics of the implementation of the objectives of this resolution, particularly in the smaller metropolitan and rural areas.

Resolutions on General Practice Residencies

Dr. Allen T. Stewart, Texas, presented the following resolutions, which were referred to the Reference Committee on Medical Education and Hospitals:

Whereas, It is to the best interest of the people of this nation and the medical profession as a whole to have well trained family doctors in sufficient number to care properly for the sick; and

Whereas, The General Practice Residency as now set up by the Council on Medical Education and Hospitals of the American Medical Association and contained in the Essentials of Approved Residencies and Fellowships is woefully inadequate in surgical training; and

Whereas, The final result of such inadequacy can only produce in the course of time men wholly unprepared to meet the needs of the people whom they serve, with general dissatisfaction of the men engaging in the general practice of medicine, and finally discrediting of the entire medical profession; therefore be it

Resolved, By the House of Delegates of the Texas Medical Association that a better balanced training be given men serving General Practice Residencies with at least eight months out of the 24 devoted to surgery, four of which shall embrace operating room experience as assistant in major surgery, the remaining four months as now recommended for General Practice Residencies; and be it further

Resolved, That the delegates from Texas to the American Medical Association be and are hereby instructed to use every means at their command to have remedied the plan for General Practice Residencies as set forth above, and that they be further instructed to report at their first opportunity progress made in presenting this resolution.

REPORT OF REFFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, submitted the following report, which was duly adopted:

Your Reference Committee on Medical Education and Hospitals reviewed the resolutions presented by the Texas delegation, which were thoroughly considered and witnesses heard.

Your committee feels that no rigid, nationwide context should be made regarding the internship training. The present military emergency restricts all internships to one year.

Your committee recommends, and the Texas delegation agrees, that this problem and the resolutions be given to the Council on Medical Education and Hospitals for further study.

Resolution on Request for Section on Public Relations

Dr. Floyd S. Winslow, New York, presented the following resolution which was first referred to the Council on Scientific Assembly for review and then, after the report from the Council, to the Reference Committee on Sections and Section Work:

Whereas, Public relations have assumed a position of great importance in the existence of both community and physician; and

Whereas, There is much literature coming frequently to all members of the American Medical Association; and

Whereas, The assimilation of such literature regarding public relations is frequently difficult because of its volume and scope; therefore be it

Resolved, That the American Medical Association establish a Section on Public Relations as part of its Scientific Assembly in accordance with Article 9, Section 3, of the Constitution.

Report of Council on Scientific Assembly

Dr. Charles H. Phifer, Acting Chairman, presented the following report, which was duly adopted and referred to the Reference Committee on Sections and Section Work, together with the original resolution:

The Council on Scientific Assembly has carefully considered the resolution which was introduced by Dr. Floyd S. Winslow and referred to this Council.

It is the considered opinion of the members of the Council on Scientific Assembly that while good public relations should be closely associated with the practice of medicine, the subject of public relations does not fall within the meaning of Article 9, Sections 1, 2 and 3 of the Constitution in its definition and interpretation of the science and art of medicine. In view of these facts the creation of a Section on Public Relations as part of the Scientific Assembly would violate Article 9, Sections 1, 2 and 3 of the Constitution of the American Medical Association.

Your Council on Scientific Assembly therefore recommends that this resolution be not adopted.

In connection with the consideration of this resolution on public relations your Council on Scientific Assembly would like to call the attention of the members of this House of Delegates to the very excellent program on public relations arranged by the Trustees and officers of the American Medical Association which has been presented immediately prior to the opening of the clinical sessions of the Association. This should be attended by the members of the House of Delegates.

Report of Reference Committee on Sections and Section Work

Dr. Willard A. Wright, Chairman, submitted the following report, which was duly adopted:

Your committee had referred to it the request for the formation of a new Section on Public Relations; also the Report of the Council on Scientific Assembly recommending that this Section on Public Relations be not formed. Your committee concurs in the recommendation of the Council on Scientific Assembly that a new Section on Public Relations be not formed.

Your reference committee desires to recommend to the Board of Trustees that continued efforts be made to increase the interest, education and participation by physicians in public relations.

Your Reference Committee wishes to commend the Council on Scientific Assembly for the excellent programs presented at the various sessions.

Resolutions on Sales Promotion Methods of Pharmaceutical Houses

Dr. F. H. Muller, for the Illinois State Medical Society, introduced the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, The Press Relations Committee of the Chicago Medical Society has received many complaints relative to the sales promotion methods used by some of the pharmaceutical houses through the press, radio and television; and

Whereas, Their appeal is directed in many instances to the public, by-passing the medical profession and disregarding established standards; therefore be it

Resolved, That the Chicago Medical Society record its objection to these practices and direct that copies of this resolution be sent to all metropolitan press, radio and television services and that the Editor of The Journal of the American Medical Association comment on the same; and be it further

Resolved, That the delegates of the Chicago Medical Society to the Illinois State Medical Society present this matter to the Illinois State Medical Society, requesting it to take cognizance of this situation and bring the same to the attention of the American Medical Association for appropriate action looking to the correction of this situation.

(For report of Reference Committee on Miscellaneous Business, see its report on Resolution on Lay Advertising.)

Resolution on Distribution of Interns

Dr. F. H. Muller, for the Illinois State Medical Society, submitted the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The present method of securing interns in hospitals is obviously unfair to the small nonteaching hospital; and

Whereas, The patients in these small hospitals are entitled to the same high type of medical service rendered in the larger hospitals; therefore be it

Resolved, That the Council on Medical Education and Hospitals be requested to study this problem further in the interest of a more equitable distribution of interns, the apportionment being based on the number of beds in hospitals approved for intern training.

Report of Reference Committee on Medical Education and Hospitals

Dr. William Bates, Chairman, submitted the following report, which was duly adopted:

As any constructive answers to the Illinois State Medical Society's Resolution on Distribution of Interns and the Resolution on Distribution of Interns from the Ohio State Medical Association are dependent on the investigation being instituted by the Board of Trustees, this committee commends those societies for their constructive thinking. It recommends serious consideration by the Advisory Committee of our recommendation for speed. The present cooperation between the Council on Medical Education and Hospitals and the official governing bodies of interns in the various states as well as the present vicious financial bidding for intern services are dependent on an early solution of this new investigating committee.

Resolution on Blue Cross Benefits

Dr. J. D. Hancock, Kentucky, presented the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

Whereas, Blue Cross hospitalization insurance plans are usually limited by their corporate laws to pay benefits to hospitals only; and

Whereas, It appears desirable from both an economic and public service aspect that such plans should pay benefits in emergency cases for use of office facilities and supplies to a physician; and

Whereas, *Emergency medical service needs to be rendered in a hospital*, but a subscriber to Blue Cross must receive such treatment in a hospital in order to receive the benefits; and

Whereas, In many areas additional costs are incurred transporting the patient to the hospital when the emergency care could more properly and efficiently be rendered in a physician's office; and

Whereas, Revisions in the Blue Cross policy to provide payment to physicians for use of their facilities in treatment of emergency cases would result in a savings to the Blue Cross plan and a resultant conservation of *the funds available for benefits of their insured; now therefore be it*

Resolved, That this House of Delegates instruct its Council on Medical Service to study the matter of payment for emergency care under Blue Cross plans and report its recommendations at the next session of this House of Delegates.

Report of Reference Committee on Insurance and Medical Service

Dr. William R. Brooksher, Chairman, presented the following report, which was duly adopted:

Resolution on Blue Cross Benefits: Your committee recommends disapproval of this resolution for the reason that the resolution proposes the study of payment for emergency medical service under Blue Cross plans and your committee feels that payments for such service should be made by medical care plans.

Resolution on Hospital Standardization Program

Dr. George Earl, Minnesota, submitted the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The hospital standardization program carried on by the American College of Surgeons is and should be continued by physicians, rather than by lay organizations, such as the American Hospital Association; and

Whereas, The American College of Surgeons has indicated its inability to carry on this program unassisted; and

Whereas, The American Medical Association comprises and represents the American medical profession; *therefore be it*

Resolved, That the American Medical Association singly, or in combination with the American College of Surgeons, continue and maintain the hospital standardization program in its traditional form.

(For report of the Reference Committee on Medical Education and Hospitals, see its report under Report of Board of Trustees.)

(To Be Continued)

MEDICAL NEWS

ARIZONA

County X-Ray Survey.—The Maricopa County chest x-ray survey finished its nine-week drive April 21. During the drive more than 176,000 x-rays were taken, representing 75.9% of the county's eligible population, persons 15 years of age and older. The county placed sixth percentage-wise among 13 areas in the United States having similar anti-tuberculosis surveys. The state health department's chest x-ray mobile unit, which participated in the Maricopa County drive, is proceeding with the program scheduled for communities in Navajo, Apache, Mohave, and Coconino counties.

COLORADO

Annual Rocky Mountain Cancer Conference.—This fifth annual conference will be held in Denver July 11-12, sponsored by the Colorado State Medical Society and the Colorado Division of the American Cancer Society. The guest speakers are Drs. W. Edward Chamberlain, radiology, Philadelphia; Oscar T. Clagett, surgery, Rochester, Minn.; G. Edmund Haggart, orthopedics, Boston; John H. Lamb, dermatology, Oklahoma City; Walter L. Palmer, internal medicine, Chicago; John Rock, gynecology, Boston; Frank B. Queen, pathology, Portland, Ore., and Robert A. Scarborough, proctology, San Francisco.

New Clinic for Denver.—A $264,912 grant from the Commonwealth Fund of New York to the University of Colorado and the City and County of Denver will be used to improve the education of doctors for general practice and to provide better care for the indigent of Denver through the establishment of a general medical clinic at the Denver General Hospital. Organization and recruiting of the staff is now underway. The clinic will be organized so that one doctor will be in charge of each case and will be responsible for all referrals, including any appointments with specialists, or for special laboratory work. A unique aspect of the clinic will be the opportunity afforded to the staff to draw on public health and preventive medicine services. In terms of economy, the general medical clinic will reduce the reduplication of administrative work and cut down the cost of inpatient care, because the diagnostic and laboratory examinations can be done on an outpatient basis. In addition to medical staff, nursing personnel, and laboratory technicians, the clinic will also have a social worker and psychiatrist.

ILLINOIS

Society Elections.—At the annual meeting of the Illinois chapter of the American College of Chest Physicians May 23 the following officers were elected: Dr. Charles K. Petter, Waukegan, president; Drs. William J. Bryan, Rockford, vice president, and Abel Froman, Chicago, secretary-treasurer.——The following members of the Illinois Psychiatric Society were elected to office May 19: Dr. William H. Haines, Chicago, president; Dr. Jules H. Masserman, Chicago, vice president, and Dr. Josephine M. Chapin, Chicago, secretary-treasurer.

Northwestern Presents Honorary Degrees.—At the centennial year commencement exercises of Northwestern University in Evanston June 11 an honorary doctor of science degree was presented to Dr. Helen B. Taussig, professor of pediatrics, Johns Hopkins University Medical School, Baltimore, in recognition of her studies and writings as having "contributed to the understanding of congenital heart disease in children." Percy L. Julian, Ph.D., director of research for Glidden Company, Chicago, received an honorary doctor of science degree in recognition of his investigations of the products of living organisms and his work in synthesizing hormones of the gonads and adrenal cortex from soy bean steroids. Dr. Joseph C. Hinsey, dean of Cornell University Medical College, New York, received an honorary doctor of science degree in recognition of his "noteworthy contributions to medicine as a teacher, investigator in the field of neuro-anatomy, administrator, and editor and writer for medical journals." Mrs. Spencer Tracy, president of the board of directors of the John Tracy Clinic, Los Angeles, was also given an honorary doctor of science degree as a "spokeswoman for the needs of the young deaf child."

Chicago

Student Prizes.—Robert J. Maganini, third-year medical student, has been awarded the 1951 Leo F. Miller Prize of $50 at the University of Illinois College of Medicine for his presentation of an essay in the field of orthopedic surgery. The prize-winning essay was entitled "Solitary Unicameral Bone Cyst." A second place award of $15 was presented to William S. Johnson for his paper on "Traumatic Injuries of the Menisci." George A. Hart received the third place prize of $10 for his essay on "Spondylolisthesis."

Research Institutes.—Informal dedication of the University of Chicago's 11 million dollar laboratories was held May 16. The laboratories include the Institute for Nuclear Studies, the Institute of Radiobiology and Biophysics, and the Institute for the Study of Metals. Equipment includes a synchrocyclotron that will produce a beam of particles known as mesons. About 15% of the eventual working time of the beam will be spent in biological experimentation. In addition, there are a 100 million volt betatron and two other atom smashers, a Van de Graaff generator, which produces a proton beam of two million electron volts, and a 600,000-volt kevatron.

Personals.—Dr. Harry F. Dowling, professor and head of the department of preventive medicine, University of Illinois College of Medicine, Chicago, has been appointed professor and head of the department of internal medicine at the university, effective Sept. 1. He will succeed Dr. Robert W. Keeton, who will retire from active service at the end of the current academic year.——Dr. Lowell T. Coggeshall, chairman of the department of medicine of the University of Chicago, has been appointed chairman of the committee on medical sciences of the Department of Defense Research and Development Board. He replaces Dr. Francis G. Blake of Yale University, who had been chairman since April, 1948. Dr. Blake's replacement is in line with the Research and Development Board policy of rotating committee chairmanships.——Dr. Robert M. Bloch, professor of medicine at the University of Chicago clinics, has been appointed chief of the division of pulmonary diseases at Montefiore Hospital for Chronic Diseases in New York, effective Aug. 1.

KENTUCKY

Joint Meeting.—The Christian County Medical Society and the Third Councilor District of the Kentucky State Medical Association held a joint dinner meeting at the Western State Hospital, Hopkinsville, June 12. The speakers were Dr. Robert M. Coleman, Hopkinsville, "Clinical Problems and Radiation Sickness," and Dr. Roy H. Moore Jr., Louisville, "Mass Treatment of Traumatic Injuries." The meeting closed with a film entitled "Medical Aspects of the Atomic Bomb, Clinical Problems."

Rural Scholarship Fund.—A dinner meeting of the Rural Kentucky Medical Scholarship Fund was held in Louisville May 30 in honor of the June graduates of the University of Louisville School of Medicine who had received aid from the fund. All students and former graduates interning or practicing who had been granted assistance,. together with new applicants, were invited. At the business session following the dinner loans were approved for 16 students in the University of Louisville School of Medicine and one student at St. Louis University School of Medicine, all of whom had received prior loans from the fund. Ten of 12 applicants for first loans were interviewed and approval granted. Of the 49 students aided by the fund, eight graduates are in practice, and five will begin practice in July.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

MAINE

Personal.—Clarence Cook Little, Sc.D., Bar Harbor, received from Boston University the honorary degree of doctor of science at commencement exercises June 4. Dr. Little is director of the Roscoe B. Jackson Memorial Laboratory.

Annual State Medical Meeting.—The Maine Medical Association held its annual session at Poland Spring June 17-19 under the presidency of Dr. Foster C. Small, Belfast. Out-of-state speakers included:

Edward L. Howes, New York, Corticotrophin (ACTH) and Cortisone in Surgery.
Edward S. Judd Jr., Rochester, Minn., Surgery of the Thyroid Gland.
H. Bristol Nelson, Boston, Obstetrics for the General Practitioner.

At a dinner Dr. John W. Cline, San Francisco, President of the American Medical Association, was the speaker. Gov. Frederick G. Payne delivered the address at the banquet. The woman's auxiliary met in conjunction with the association.

MINNESOTA

Drs. Hench and Kendall Receive First Criss Award.—Because of their work in the development and use of cortisone, Dr. Philip S. Hench and Edward C. Kendall, Ph.D., of the Mayo Clinic, Rochester, were named joint winners of the first $10,000 Dr. C. C. Criss Award of Mutual of Omaha. Presentation of the award was made at the meeting of the American Rheumatism Association at Atlantic City on June 9. Dr. Elmer L. Henderson, then President of the American Medical Association, introduced Dr. Neil L. Criss, medical director and treasurer of Mutual of Omaha, who presented each of the winners $5,000 and a gold medal. The Criss award was created in 1949 in honor of the founder and chairman of the board of the health and accident insurance company. It is awarded to the person or persons residing in the United States, Canada, Alaska, or Hawaii, who, in the opinion of the board of judges, make the greatest contribution to public health and/or safety each year.

NEBRASKA

Fluoridation of Water.—Beatrice is the first city in Nebraska to officially approve fluoridation of its municipal water supply for the partial control of dental caries. Superior has also officially approved the fluoridation of its public water supply and is taking steps to get the program in operation as soon as possible.

NEW YORK

University Appointment.—Dr. Frederick H. Hesser, who has been assistant professor of neurology at the State University of Iowa College of Medicine in Iowa City since 1948, has been appointed associate professor of neurology at Albany Medical College. He has also been appointed attending neurologist at Albany Hospital and will be in charge of the brain wave recording laboratory there.

Dr. Collier Awarded Kaiser Medal.—At the annual meeting of the Rochester Academy of Medicine Dr. G. Kirby Collier, Rochester, was presented the Albert David Kaiser Medal, the highest award of the academy, "in recognition of his services to humanity." Dr. Collier has been a physician in Rochester since 1919. He is chairman of the section on convulsive disorders of the American Psychiatric Association and of the committee on nervous and mental diseases of the Medical Society of the State of New York.

New York City

City Suspends Immunization for Summer.—The New York City Department of Health has suspended immunizing infants and children over 6 mo. of age against diphtheria and whooping cough at the department's 76 child health stations from June 15 to Oct. 1 this year. This action is being taken because of a possible relation between recent immunization and paralysis in poliomyelitis.

Dr. Gorham Heads Public Health Institute.—The Public Health Research Institute of the City of New York, Inc., has appointed Dr. L. Whittington Gorham of Albany as director to succeed the late Dr. Walter W. Palmer. Dr. Gorham has been a member of the Public Health Council of New York State for 11 years and chairman since 1947. He served as professor of medicine at Albany Medical College from 1937 to 1948 and physician-in-chief of the Albany Hospital. Since 1948 he has been professor of medicine and coordinator of the division of oncology in the medical school and senior physician in the hospital. The Public Health Research Institute was organized in 1941 as a nonprofit membership corporation organized for the purpose of undertaking research and investigation into problems of public health.

Personals.—Dr. Frank R. Ferlaino, medical director in New York for General Motors Corporation and assistant clinical professor of industrial medicine at New York Postgraduate Medical School, has been made a trustee of the Society of Medical Jurisprudence, succeeding Dr. L. Howard Moss, Richmond Hill, resigned.——Dr. Samuel Rosen, associate otologist at the Mt. Sinai Hospital, has accepted an invitation from the Ministry of Health in Israel to visit that country for a tour of lectures and guest operations. Dr. Rosen will work at Tel Aviv, Haifa, and Jerusalem.——At the recent 75th anniversary meeting of the American Dermatological Association Dr. Howard Fox was made an honorary member of the association. His father, Dr. George H. Fox, was one of the founders of the association.

OHIO

University Alcoholism Clinic.—The Alcoholism Clinic, seventh subdivision of the outpatient activities of the University of Cincinnati department of psychiatry, will accept its first patients on Aug. 1. The new clinic is to be supported financially by a group of industrialists organized as a Committee of the Public Health Federation.

Cincinnati Society of Internal Medicine.—This society was organized on May 18. The executive committee elected includes Dr. Joseph N. Ganim, president; Dr. W. Orville Ramey, vice president; Dr. George X. Schwemlein, secretary-treasurer; Dr. Marion A. Blankenhorn, Dr. Harold K. Moss, and Dr. Robert M. Woolford. The society will hold monthly meetings.

SOUTH CAROLINA

New University Medical Center.—The first contracts have been let for the construction of the new Medical College of the State of South Carolina 400-bed teaching hospital. In addition, new laboratory, clinic, and library expansion of the existing plant have been made possible by an appropriation from the state legislature and a grant from the National Cancer Institute. Land has been acquired for the erection of a new dormitory building for students and some of the staff. Arrangements are virtually complete for the erection of a new tuberculosis hospital in connection with this medical center. Funds available to carry out the construction program amount to over 12 million dollars, not including dormitory construction. The South Carolina Medical Association on May 15 appropriated $10,000 for the use of the Medical College of the State of South Carolina in connection with the proposed increase in its enrollment.

TEXAS

Study of Burns.—The T. J. Brown and C. A. Lupton Foundation has given a grant of $18,000 to the University of Texas Medical Branch, Galveston, to support a fellowship in the division of plastic surgery under the direction of Dr. Truman G. Blocker Jr. The grant, which will be used to assist in studies on methods of treating severe burns, includes provision for technical assistants as well as for special equipment.

WASHINGTON

Addition to Children's Orthopedic Hospital.—Ground was broken May 14 for the Children's Hospital in Seattle, which is to cost 4½ to 5 million dollars and be an addition to the Children's Orthopedic Hospital. The 200-bed institution is being built on the 25-acre Laurelhurst tract comparatively close to the University of Washington School of Medicine. Though the name of the hospital appears to limit it to orthopedic cases, it has grown into a general children's hospital with 36 specialized clinics. The hospital, for which an additional million dollars must be raised, is scheduled for completion early in 1953.

GENERAL

Childrens Aid Ends in Greece.—The *New York Times* reported June 7 that after 3½ years of mission work in Greece the United Nations International Children's Emergency Fund has announced that its work in that country would come to an end on June 30. The total value of food and supplies shipped by the fund during that time amounted to eight million dollars, and clothing and health projects cost $756,000.

Books Reach Japanese Hospital.—The first medical books to reach the Cooperative Hospital of Nakano-ku, Tokyo, in more than a decade have been received by the institution's founder, Dr. Toyohiko Kagawa. The books were sent by the Cooperative League Congress, Chicago, through the CARE-UNESCO Book Fund Program. The shipment included five up-to-date works on bacteriology, anatomy, anesthesia, and medical principles and practice valued at $51.50. Medicine is one of 21 book categories that are acceptable by the Book Fund, CARE, 20 Broad St., New York 5, or any CARE office in the United States.

American Orthopaedic Association.—This association held its annual session June 20-23 at the Greenbrier, White Sulphur Springs, W. Va., under the presidency of Dr. James S. Speed, Memphis. Dr. Fremont Chandler, Chicago, was installed as the new president at this meeting. Those presenting papers by invitation were:

Robert Robinson, Rochester, N. Y., Inorganic Component of Bone as Demonstrated by the Electron Microscope.
Robert D. Ray, Seattle, A Comparative Study of Bone Grafting Materials.
Charles H. Herndon, Cleveland, Experimental Studies in Transplantation of Whole Joints.
Ian Macnab, Toronto, Canada, Recurrent Dislocation of the Patella.
George T. Pack, New York, Sarcomas of the Soft Somatic Tissues.
Harold R. Bohlman, Baltimore, Replacement Reconstruction of the Hip.
Arthur W. Ham, Toronto, Canada, Histophysiological Problems Peculiar to Calcified Tissues.
William T. Mustard, Toronto, Iliopsoas Transfer for Hip Abductor Weakness.

Cerebral Palsy Scholarships.—Alpha Chi Omega, national women's fraternity, and the National Society for Crippled Children and Adults, have jointly announced the names of six recipients of specialized scholarships in cerebral palsy. Those receiving scholarships include Mrs. Ruth E. Cook, teacher in charge of the Nursery School for Cerebral Palsied Children, Phoenix, Ariz.; Frederick Darley, Ph.D., assistant professor of speech, State University of Iowa, Iowa City; Murray M. Halfond, speech pathologist, Duke University School of Medicine, Durham, N. C.; Marilyn J. Hill, nursery school teacher at the Meeting Street School in Providence, R. I.; Betty Jane McWilliams, speech therapist at the Cerebral Palsy School maintained by the Wheeling Society for Crippled Children, Wheeling, W. Va., and Mrs. Alice S. Noel, education director of the Cerebral Palsy Pre-School of Vine Hill, Nashville, Tenn. The cerebral palsy scholarship program is made possible by a financial grant established in 1948 by Alpha Chi Omega, which has taken the welfare of the cerebral palsied as its major altruistic project. In the past three years 54 scholarships have been awarded.

Society Elections.—At the annual meeting of the Society for Investigative Dermatology in Atlantic City, N. J., June 7-8, Dr. Samuel M. Peck, New York, was elected president, and Dr. John R. Haserick, Cleveland, vice president. Dr. Marion B. Sulzberger, New York, was elected a member of the board of directors of the society for a period of five years, 1951-1956.——At the annual meeting of the American Psychoanalytic Association in Cincinnati May 3-6 the following took office for 1951-53: Dr. Robert P. Knight, Stockbridge, Mass., president; Dr. Ives Hendrick, Boston, president-elect; Dr. LeRoy M. A. Maeder, Philadelphia, secretary, and Dr. William G. Barrett, San Francisco, treasurer. The Brill Memorial Medal was presented to the retiring president, Dr. M. Ralph Kaufman, New York.——At the annual meeting of the American Heart Association in Atlantic City June 6-10 Dr. Louis N. Katz, director of cardiovascular research, Michael Reese Hospital, Chicago, became president succeeding Dr. Howard B. Sprague of Brookline, Mass., who, by custom, will become chairman of the scientific council. Dr. Irving S. Wright, professor of clinical medicine, Cornell University, New York, was chosen president-elect. The number of vice presidents was increased from one to five, and the following were elected to fill these posts: Mrs. Alben Barkley, Washington, D. C.; Bruce Barton, New York; Dr. T. Duckett Jones, New York; Dr. Robert L. King, Seattle, and Frederick K. Trask Jr., New York. Grant Keehn, New York, was renamed treasurer of the association.

International Anesthesia Research Society.—The Congress of Anaesthetists, a joint session of the International Research Society and the International College of Anaesthetists, will be held at the British Medical Association House, Tavistock Square, London, Sept. 3-8. Among those appearing on the program are the following:

Nadia de Bouchet, Paris, Electro-Cardiographic Changes During Cardiac Surgery.
I. C. W. English, London, Role of Selective Bronchial Intubation in Thoracic Surgery.
P. Mazzoni, Rome, Anesthesia for Cardio-Vascular Surgery.
Salomon N. Albert, Lebanon, Anesthesia for Pulmonary Partial Resections.
H. C. Voorhoeve, Delft, Holland, Post-Operative Analgesia.
S. R. Johnson, Stockholm, Sweden, Circulatory Studies During Anesthesia by Means of Heart Catheterization.
D. S. Wilson, Londonderry, N. Ireland, Anesthesia for the Aged.
Harold R. Griffith, Montreal, Canada, Safety Factors in Spinal Anesthesia.
E. Lopes Soares, Lisbon, Portugal, General Anesthesia with Pentothal-Novocain.
Owen Elder, Buenos Aires, Argentina, Modern Anesthesia in Argentina.

The Hewitt Lecture will be given the afternoon of Sept. 4 by Dr. Robert M. Tovell, director of anesthesiology, Hartford Hospital, Hartford, Conn., on "New Horizons in Anesthesiology."

An International Congress of Anesthesiology will take place in Paris Sept. 20-22 in the Nursing School of the Hospice de la Salpetreiere, (The Journal, June 2, p. 486).

Report of World Health Assembly.—With the participation of 70 countries and 20 international organizations, the World Health Assembly opened in Geneva on May 7 and met for 16 days under the chairmanship of Dr. Leonard Scheele, Surgeon-General, U. S. Public Health Service. Most important achievement of the assembly legislative body of the World Health Organization was the adoption of international sanitary regulations, which, without need for ratification by member states, will automatically come into force on Oct. 1, 1952 and replace all existing sanitary conventions for health protection in international trade and travel. The assembly's decisions on program questions mean that for the first time there will be, next year, a world-wide coordinated pattern of international health work financed by WHO, the United Nations International Children's Emergency Fund, and the United Nations technical assistance program. WHO's 1952 program will represent the first phase in carrying out a four-year plan that stipulates short and long-term objectives for building strong national health services throughout the world. The assembly set an effective working budget of almost $7,700,000, a 25% increase over this year's figure. Another feature of the assembly was a series of informal technical discussions on the education and training of medical and public health personnel. The discussion underlined the pressing need for reform of the curriculum of medical schools and related institutions and for reorientation of teaching toward preventive medicine and social medicine. Three countries, Japan, Spain, and Germany, were admitted to WHO, increasing membership to 78 countries, although 10 are now inactive. Six countries, Cuba, Belgium, Lebanon, Liberia, Ceylon, and Greece, were elected to the executive board replacing Yugoslavia, Union of South Africa, the Netherlands, Brazil, Poland, and India. The World Health Assembly honored the Belgian scientist, Dr. Rene Sand, who was awarded the Leon Bernard Foundation Prize for his achievements in social medicine.

LATIN AMERICA

Pan-American Congress Against Tuberculosis.—This congress will be held July 14-22 in Guayaquil, Ecuador. There will be official delegates of several Pan-American countries. Official speakers listed on the preliminary program include: Drs. Ramón Vargas Machuca and Victor M. Tejada, both of Perú, on "Antibiotics in Treatment of Tuberculosis," and Drs. Jorge Campos R., Víctor Narváez, Juan J. Arredondo and Ricardo Subiría of Perú on "Circulation in Pulmonary Tuberculosis," Drs. Ramón

E. Marín Pittaluga and Abelardo Rodríguez of Uruguay on the general topic tuberculosis and Miguel A. Fierro Vignoli, Mario Volonterio, and Luis E. Magnone on "National Findings in Massive Examination of Chest in Uruguay." Drs. Jorge A. Higgins, Francisco Marchán, Armando Pareja Coronel, José Durand N. and Euro Torres L., Marcos Martínez M., all of Ecuador, will be speakers and co-speakers on the clinical surgical and laboratory aspects of tuberculosis and paraaminosalicylic acid and tuberculin in treatment of tuberculosis.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 5-7 (Part I only). Applications must be filed at least thirty days prior to an examination. Ex. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

INTERNATIONAL COLLEGE OF SURGEONS

Examinations for Certified Fellowship in the United States Chapter in General and Orthopedic Surgery, Chicago, Aug. 3-4. Sec., Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago 10.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* July 20. Given simultaneously in several cities in the United States. Final date for filing application was Jan. 20. *Oral.* Memphis, Oct. 14-17. *Written.* July 18, 1952, Various locations. Final date for filing applications is Jan. 18, 1952. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Internal Medicine: *Written.* Various centers, Oct. 15. Final date for filing applications was May 1. *Oral.* The schedule of oral examinations for 1951 has been arranged on a regional basis as follows: New York, date to be announced, covering Maine, Massachusetts, New Hampshire, New York and Vermont. San Francisco, date to be announced, covering Arizona, California, Colorado, Idaho, Montana, New Mexico, Oregon, Utah and Washington.

Only candidates who have not taken an oral examination can be admitted under the schedule arranged thus far.

Dates of closing dates for the filing of applications for examinations in New York and San Francisco to be announced.

Oral examinations in the subspecialties will be held at the same time and place and on the same distribution.

Exec. Sec., Dr. William A. Werrell, 1 West Main Street, Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, Oct. 25-26. *Oral.* Chicago, May 1952. Final date for filing applications for the May 1952 examination is Jan. 1, 1952. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: *Written.* Feb. 1, 1952. Final date for filing applications is Nov. 1. *Oral.* Chicago, June 7-13, 1952. Final date for filing application is Feb. 1, 1952. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, Pa.

American Board of Ophthalmology: *Written.* Twenty-five centers, Feb. 4-5, 1952. *Oral.* Chicago, October 8-13. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: Final date for filing applications for the 1952 Part II examinations is Aug. 15, 1951. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 8-12. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pediatrics: *Oral.* Buffalo, Oct. 26-28. Ex. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Preventive Medicine: *Written.* San Francisco, October 28. *Oral.* San Francisco, October 29. Sec., Dr. Ernest L. Stebbins, 615 North Wolfe St., Baltimore 5.

American Board of Proctology: Philadelphia, Nov. 17-18. Sec.-Gen., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Washington, D. C., Sept. 17-22. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various centers, Oct. 1951. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 South 15th Street, Philadelphia.

Board of Throacic Surgery: *Written.* Various parts of the country. Sept. 14, 1951. Final date for filing applications is July 15. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: Chicago, Feb. 9-13, 1952. Final date for filing applications is Sept. 1. Sec., Dr. Harry Culver, 314 Corn Exchange Bldg., Minneapolis 15.

MEETINGS

Natinoal Medical Association, Philadelphia, Aug. 20-24. Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va., General Secretary.

Postgraduate Assembly in Endocrinology, Olympic Hotel, Seattle, Wash., July 2-7. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City, Okla., Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Reno Surgical Society Conference, Riverside Hotel, Reno, Nev., Aug. 23-25. Dr. Olin C. Moulton, 130 N. Virginia St., Reno, Nev., Chairman.

Rocky Mountain Radiological Society, Denver, Aug. 9-11. Dr. Maurice D. Frazer, 1037 Stuart Building, Lincoln, Nebr., Secretary.

West Virginia State Medical Association, The Greenbrier, White Sulphur Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

Association Internationale de Psychotechnique, Gothenburg, Sweden, July 24-28. Dr. Franziska Baumgarten-Tramer, Thunstrasse 35, Berne, Switzerland.

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6^e^, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19. Mrs. Grace E. O'Neill, Division of World Affairs, National Association on Mental Health, 1790 Broadway, New York 19, N. Y.

International Congerss of Physical Medicine, London, England, July 14-19. Dr. A. C. Boyle, 45, Lincoln's Inn Fields, London, W.C.2, England, Honorable Secretary.

International Congress of Psychology, Stockholm, Sweden, July 16-21. Secretariat: Psychological Institute, Observotoriegatan 8, Stockholm, Sweden.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan American Congress on Tuberculosis, Guayaquil and Quito, Ecuador, S. A., July 14-22. Dr. Marco Martinez M., Casilla de Correos No. 116, Guayaquil, Ecuador, Secretary General.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physicial Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary-General.

DEATHS

Hazen, Henry Honeyman ⊕ Washington, D. C.; born in Oldwick, N. J., July 21, 1879; Johns Hopkins University School of Medicine, Baltimore, 1906; professor of dermatology emeritus at Howard University College of Medicine, where he had been professor from 1911 to 1944 and director of postgraduate courses in venereal disease control from 1937 to 1942; professor of dermatology at Georgetown University School of Medicine from 1913 to 1934; a member of the Committee on Evaluation of Serodiagnostic Tests for Syphilis, since 1926 consulting dermatologist, and since 1943 chairman of the Advisory Committee on Public Education for the Prevention of Venereal Diseases, U. S. Public Health Service; consultant in syphilology and from 1942 to 1946 attending physician to the District of Columbia Health Department; honorary life member of the American Social Hygiene Association; president of the Social Hygiene Society of the District of Columbia from 1937 to 1945; member of the American Dermatological Association; specialist certified by the American Board of Dermatology and Syphilology; chairman of the National Prophylactic Committee; visiting dermatologist to the Columbia Hospital for Women and Lying-In Asylum and Freedmen's Hospital; in 1944 awarded an honorary doctor of science degree by Howard University and in 1925 received an honorary master of arts degree from Georgetown University; author of "Diseases of the Skin," 1915, third edition in 1927, "Skin Cancer," 1916, "Syphilis," 1919, second edition 1928, "Cutaneous X-ray and Radium Therapy," 1931, and "Syphilis in the Negro," 1942; died May 1, aged 71.

Hamilton, Paul Myron ⊕ San Marino, Calif.; born in Brightwood, Ind., July 19, 1894; Johns Hopkins University School of Medicine, Baltimore, 1922; clinical professor of pediatrics at the University of Southern California School of Medicine; specialist certified by the American Board of Pediatrics; certified by the National Board of Medical Examiners; member of the American Academy of Pediatrics, the Southwestern Pediatric Society, of which he was a past president, the medical advisory board, Los Angeles branch, National Foundation for Infantile Paralysis, the Los Angeles Academy of Medicine, and the Medical Symposium Society of Los Angeles; on the staff of the Los Angeles County General Hospital, where for 12 years he served as chief of the communicable disease unit; for many years senior staff member and in 1950 president of the Huntington Memorial Hospital in Pasadena, where in perpetuation of his good works the Paul Hamilton Memorial Fund has been established to assist the care of needy children in the pediatric ward; consultant at St. Luke Hospital in Pasadena; died March 9, aged 56, of coronary occlusion.

Herbst, Robert Harry ⊕ Highland Park, Ill.; born in Chicago Dec. 25, 1877; Rush Medical College, Chicago, 1900; specialist certified by the American Board of Urology; professor of urology, emeritus, at the University of Illinois College of Medicine; formerly clinical professor of surgery (genito-urinary) at his alma mater; member and past president of the American Urological Association, Chicago Urological Association, and the Rush Medical Alumni Association; fellow of the American College of Surgeons; member of the Institute of Medicine of Chicago and the Chicago Society of Medical History; attending urologist at Presbyterian Hospital, Chicago, and the Lake Forest Hospital; attending genitourinary surgeon, Highland Park Hospital, died May 15, aged 73, of cerebral hemorrhage.

Kordenat, Ralph August ⊕ St. Louis; born in Reedsburg, Wis., May 1, 1894; University of Illinois College of Medicine, Chicago, 1922; member of the founders group of the American Board of Surgery; formerly associate professor of surgery at his alma mater; fellow of the American College of Surgeons; at one time practiced in Chicago, where he was on the staff of Henrotin Hospital; Veterans Administration area chief of surgery for eight states since 1948; served during World War I; during World War II vice medical chairman of Cook County for the Procurement and Assignment Service; died in the Veterans Administration Hospital, Jefferson Barracks, May 9, aged 57, of coronary occlusion following cervical laminectomy.

Gresser, Edward Bellamy ⊕ New York; born in New York April 29, 1898; University and Bellevue Hospital Medical College, New York, 1922; associate professor of ophthalmology at his alma mater, now known as New York University College of Medicine; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; consultant in tropical ophthalmology to the Secretary of War from 1943 to 1949; affiliated with Beth Israel, Lincoln, and Bellevue hospitals; died in Trudeau, N. Y., April 28, aged 53, of bronchopneumonia due to monilia.

Peacock, Alexander Hamilton ⊕ Seattle; born in Philadelphia June 29, 1880; University of Pennsylvania Department of Medicine, Philadelphia, 1903; an Associate Fellow of the American Medical Association and in 1930-1931 member of its House of Delegates; specialist certified by the American Board of Urology; member of the North Pacific Surgical Association and American Urological Association; fellow of the American College of Surgeons; urologist, Kings County Hospital; on the staff of Swedish Hospital, Seattle General Hospital, Children's Orthopedic Hospital, Maynard Hospital, Columbus Hospital, and Providence Hospital, where he died April 13, aged 70, of carcinoma of the face.

Gilbert, George Burton ⊕ Colorado Springs, Colo.; Johns Hopkins University School of Medicine, Baltimore, 1907; specialist certified by the American Board of Internal Medicine; an Associate Fellow of the American Medical Association; member of the American College of Chest Physicians, American Trudeau Society, and American Clinical and Climatological Association; fellow of the American College of Physicians; associate research director of the Colorado Foundation for Research in Tuberculosis; consulting physician to Memorial Hospital; member of the honorary staff, Glockner-Penrose Hospital; associate physician, St. Francis Hospital; died April 6, aged 69, of coronary occlusion.

Nicholson, William Rufus ⊕ Philadelphia; born in Boston Feb. 26, 1868; University of Pennsylvania Department of Medicine, Philadelphia, 1893; emeritus professor of gynecology and obstetrics at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; life member of the American Gynecological Society; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the College of Physicians of Philadelphia, serving as secretary for many years; served on the staffs of the Methodist and Presbyterian hospitals and as consultant for Germantown Hospital; died Feb. 18, aged 82, of arteriosclerotic heart disease.

Myers, Thomas Chalmers ⊕ Los Angeles; University of Southern California School of Medicine, Los Angeles, 1900; an Associate Fellow of the American Medical Association; past president of the Los Angeles County Medical Association; fellow of the American College of Surgeons; active in World War I and was the recipient of the Italian Croce al Merito di Guerra; lieutenant colonel in the medical reserve corps of the U. S. Army; first staff president of St. Vincent's Hospital, serving in that capacity in 1920, and was active on the staff more than 20 years; died in St. Vincent's Hospital April 9, aged 75, of cerebral arteriosclerosis.

Davis, David Bennett ⊕ Los Angeles; University of Minnesota Medical School, Minneapolis, 1934; instructor in pediatrics at the College of Medical Evangelists, Loma Linda and Los Angeles; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; affiliated with Cedars of Lebanon Hospital, where he died April 12, aged 43, of rheumatic heart disease.

⊕ Indicates Fellow of the American Medical Association.

Flint, Oliver Josephus ⊕ Princeton, Ill.; Northwestern University Medical School, Chicago, 1898; veteran of the Spanish-American War; served during World War I; member of the high school board of Princeton Township for many years; for many years president of the Bureau County Tuberculosis Sanitary Board; affiliated with Perry Memorial Hospital, where he died March 24, aged 80, of carcinoma of the urinary bladder.

Gault, Reece C., Jackson, Ga.; Meharry Medical College, Nashville, Tenn., 1914; died March 20, aged 60, of cerebral hemorrhage, hypertension, and arteriosclerosis.

Gelb, Maurice ⊕ Montgomery, Ala.; Cornell University Medical College, New York, 1920; served during World War I; affiliated with the Veterans Administration; died in the Veterans Administration Hospital March 24, aged 56, of myocardial infarction.

Gibbons, George Lee, Mitchell, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1903; past president of the Lawrence County Historical Society; served during World War I; for two terms coroner of Lawrence County and later county health officer; for many years health officer of Mitchell; died April 13, aged 72.

Gilbert, Mabelle Spaulding Watson, East Cleveland, Ohio; Cleveland University of Medicine and Surgery, 1897; on the staffs of Huron Road and Woman's hospitals in Cleveland; died May 7, aged 77, of coronary disease.

Gilligan, Alexander, Baldwin, N. Y.; Long Island College Hospital, Brooklyn, 1899; specialist certified by the American Board of Otolaryngology; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served on the staff of Lutheran Hospital; died in Brunswick General Hospital, Amityville, April 7, aged 82.

Gooding, Harvey Burt, Germantown, Ohio; Ohio Medical University, Columbus, 1901; president of the Montgomery County Crippled Children Society; served on the staff of the Middletown (Ohio) Hospital; died recently, aged 73, of hemorrhage, esophageal varicosities and arteriosclerotic heart disease.

Govar, Claude J., North Little Rock, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1923; served during World War I; died April 30, aged 55.

Griffin, Sarah Myrtle Freeberger, Manson, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1897; member of the American Medical Association; died Feb. 28, aged 79, of myocarditis.

Hanlein, Victor ⊕ Schenectady, N. Y.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1921; served during World War I; affiliated with St. Clare's Hospital and Ellis Hospital, where he died May 13, aged 55, of coronary thrombosis.

Harned, Sophia P., Brooklyn; Hahnemann Medical College and Hospital, Chicago, 1884; served on the staff of Prospect Heights Hospital, where she died April 14, aged 90.

Harrison, John Francis ⊕ Stamford, Conn.; Jefferson Medical College of Philadelphia, 1903; member of the American Association of Industrial Physicians and Surgeons; affiliated with Stamford Hospital and St. Joseph's Hospital, where he died April 13, aged 76, of osteoporosis of the vertebrae and arteriosclerosis.

Hartman, Frank G., Lancaster, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; member of the American Medical Association; past president of the Lancaster County Medical Society; served as president of the city board of health and as county coroner; affiliated with Lancaster General Hospital; died April 30, aged 81.

Heine, Clinton Daniel ⊕ Hooper, Neb.; Rush Medical College, Chicago, 1915; died in Omaha April 28, aged 63, of acute leukemia and bronchopneumonia.

Helper, Morton ⊕ Evansville, Ind.; University of Michigan Medical School, Ann Arbor, 1936; treasurer of Vanderburgh County Medical Society; formerly on the faculty of his alma mater; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; served during World War II and was awarded the Bronze Star; affiliated with St. Mary's and Protestant Deaconess hospitals; died May 10 in Columbus, Ohio, aged 39, of Hodgkin's disease.

Henderson, Richard Alvin, Brooklyn; Long Island College Hospital, Brooklyn, 1897; member of the American Medical Association; on the staff of the Brooklyn Eye and Ear Hospital; died April 12, aged 76.

Hill, Henry Garland ⊕ Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1912; died May 4, aged 65, of coronary thrombosis.

Hise, Fred Rhodes, Canton, Ohio; McGill University Faculty of Medicine, Montreal, Canada, 1930; member of the American Medical Association; served during World War II; died recently, aged 48, of coronary thrombosis.

Horne, Joseph Alvin, Detroit; Central College of Physicians and Surgeons, Indianapolis, 1897; died April 24, aged 84, of heart disease.

Hoster, Herman Albert ⊕ Columbus, Ohio; Johns Hopkins University School of Medicine, Baltimore, 1938; professor of medicine and coordinator of oncology at Ohio State University College of Medicine; president of the Hodgkin's Disease Research Foundation; research director of Columbus Cancer Clinic; affiliated with Ohio State University Hospital, where he died May 14, aged 39, of Hodgkin's disease.

Houston, Bush ⊕ Nevada, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; fellow of the American College of Surgeons; served during World War I; second vice-president of the Iowa State Medical Society; city health officer and for six years member of the school board; surgeon for the North Western and Rock Island railroads; died in Memorial Hospital, International Falls, Minn., April 22, aged 65, of cerebral hemorrhage.

Hover, Frank William ⊕ Sealy, Texas; Long Island College Hospital, Brooklyn, 1905; died recently, aged 71, of coronary thrombosis.

Katz, Israel K. ⊕ Cleveland; University of Louisville (Ky.) School of Medicine, 1928; member of the American Trudeau Society; on the staff of Mount Sinai Hospital; served on the staff of Sunny Acres, Cuyahoga County Tuberculosis Hospital; died April 11, aged 48, of arteriosclerotic heart disease.

Kaufmann, Eugene, College Point, N. Y.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1906; member of the American Medical Association; served on the staffs of the Horace Harding Hospital in Elmhurst and Parsons Hospital in Flushing; died April 18, aged 70, of heart disease.

Kenworthey, William Bartle ⊕ Lieutenant Colonel, U. S. Army, retired, Lake Worth, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served during World War I; entered the medical corps of the U. S. Army as a captain in 1920; promoted to major in 1929; retired with the rank of lieutenant colonel in September, 1937, for disability in line of duty; died March 19, aged 77, of arteriosclerotic heart disease and prostatic hypertrophy.

Kimery, Philip Erasmus, Smithshire, Ill.; Barnes Medical College, St. Louis, 1910; member of the American Medical Association; died in Graham Hospital, Canton, April 20, aged 68, of injuries received in a truck accident.

King, Bernard Albert, Anderson, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the American Medical Association; served during World War I; died in Jackson Memorial Hospital, Miami, Fla., April 25, aged 68, of cerebrovascular accident.

Koons, Franklin Walter, Halstead, Kan.; Kansas City (Mo.) Medical College, 1898; member of the American Medical Association; past president of the Harvey County Medical Society; died April 18, aged 79.

Kremers, Alexander, Waupun, Wis.; Northwestern University Medical School, Chicago, 1905; affiliated with Central State Hospital; died April 4, aged 69.

Kreuder, Henry ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1898; died April 27, aged 78.

Kriebs, Frank Joseph, Elkport, Iowa; Rush Medical College, Chicago, 1881; member of the American Medical Association; died in Mercy Hospital, Dubuque, April 18, aged 91, of cerebral embolism.

Laffoon, Clint A., Park City, Utah; the Hahnemann Medical College and Hospital, Chicago, 1907; member of the American Medical Association and the American Association of Railroad Surgeons; formerly member of the Kansas State Board of Health; physician for the Silver King Coalition Mine and the Union Pacific Railroad; died in the Park City Miners' Hospital May 10, aged 70, of cerebral hemorrhage.

Laufman, Isidor, Cleveland; Long Island College Hospital, Brooklyn, 1908; died April 14, aged 67, of coronary thrombosis.

Lief, Frederick Paul ⊕ Kew Gardens, N. Y.; Long Island College of Medicine, Brooklyn, 1934; affiliated with Queens General Hospital in Jamaica and Bellevue Hospital in New York; died in Forest Hills April 17, aged 42, of coronary sclerosis.

McAlister, Hector Clive, Fort Wayne, Ind.; University of Toronto Faculty of Medicine, Toronto, Canada, 1916; medical director of the Lincoln National Life Insurance Company; killed in an airplane crash April 28, aged 55.

McCrea, Eppie Sabra ⊕ Eddyville, Iowa; Barnes Medical College, St. Louis, 1904; member of the public library board and the Iowa State Medical Women's Society; died April 25, aged 83, of hemiplegia.

McCullough, Walter James, Sayville, N. Y.; Jefferson Medical College of Philadelphia, 1918; died in Dr. King's Hospital, Bay Shore, April 25, aged 66, of cancer of the larynx.

McGarvey, Samuel Curtis, Bridgeville, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1901; member of the American Medical Association; member of the school board of Bridgeville for 18 years, serving part of the time as president; since 1902 on the board of the Bridgeville Trust Company, of which he had been president for many years; for eight years a member of the borough council; died in Presbyterian Hospital, Pittsburgh, April 15, aged 81, of renal insufficiency.

McKelvey, Samuel Robert, Denver; Western Reserve University Medical Department, Cleveland, 1884; member of the American Medical Association; formerly associated with the U. S. Public Health Service; at one time secretary and executive officer of the Colorado State Board of Health; died in the General Rose Memorial Hospital April 10, aged 89, of bronchopneumonia and hemorrhage following extraction of a tooth.

MacPherson, Charles Herbert, Morrisonville, Ill.; Chicago College of Medicine and Surgery, 1913; member of the American Medical Association; past president of the Christian County Tuberculosis Association; served during World War I; on the staff of St. Vincent Hospital in Taylorville; died April 8, aged 65, of coronary occlusion.

Marble, Robert Eugene ⊕ Omaha; Hering Medical College, Chicago, 1906; John A. Creighton Medical College, Omaha, 1914; affiliated with Lutheran Hospital; died in Methodist Hospital April 18, aged 68, of carcinoma.

Martin, Edward, Milton, Mass.; Tufts College Medical School, Boston, 1911; member of the American Medical Association; affiliated with the Boston City Hospital and Massachusetts Women's Hospital in Boston, and the Homberg Infirmary, Massachusetts Institute of Technology, Cambridge; died April 9, aged 66, of coronary thrombosis.

Martin, Elmer Ellsworth, Milwaukie, Ore.; Albany (N. Y.) Medical College, 1892; died in the Veterans Administration Hospital in Vancouver, Wash., April 14, aged 86.

Mayerberg, I. Wallace, Wilmington, Del.; Jefferson Medical College of Philadelphia, 1907; formerly with the medical department of the E. I. du Pont de Nemours Company; died May 2, aged 66, of gastrointestinal hemorrhage.

Mitchell, Edwin Joseph, Scottsbluff, Neb.; John A. Creighton Medical College, Omaha, 1913; also a graduate in pharmacy; died April 30, aged 70, of uremia and pneumonia.

Morgan, Richard Theodore, Marion, Ohio; Ohio Medical University, Columbus, 1897; member of the American Medical Association; member and past president of the Marion Academy of Medicine; died in Marion City Hospital April 9, aged 78, of cerebral hemorrhage.

Mueller, George ⊕ Chicago; Rush Medical College, Chicago, 1894; an Associate Fellow of the American Medical Association; formerly on the faculty of Loyola University School of Medicine; fellow of the American College of Surgeons; emeritus chief-of-staff, St. Mary of Nazareth Hospital; died May 7, aged 83, of hypostatic bronchopneumonia.

Nordenbrock, Gregory John ⊕ Dallas, Texas; Washington University School of Medicine, St. Louis, 1934; at one time health commissioner for Shelby County, Ohio; died April 20, aged 45, of coronary heart disease.

Onnen, John G. ⊕ Baltimore; College of Physicians and Surgeons, Baltimore, 1908; also a graduate in pharmacy; on the staffs of Maryland General, St. Joseph, Lutheran, and Franklin Square hospitals; chief medical examiner of the Selective Service Board during World War II; died April 18, aged 67, of arteriosclerosis and aortic stenosis.

Palmer, Paris A., Maynardville, Tenn.; University of Tennessee Medical Department, Nashville, 1893; died March 20, aged 83, of heart disease.

Pickett, Elizabeth Lovelace ⊕ Aldan, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; for many years member of the school board in Aldan and the borough council; cited by the Red Cross for her services performed during World War I; medical superintendent and owner of Pickett Sanatorium; died in Delaware County Hospital, Drexel Hill, April 14, aged 82, of intestinal hemorrhage.

Prendergast, John James ⊕ San Diego, Calif.; Loyola University School of Medicine, Chicago, 1932; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; affiliated with Mercy Hospital, where he died April 8, aged 45, of cerebral metastatic carcinoma and adenocarcinoma of the esophagus.

Rosenow, Erwin R., New York; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1909; member of the American Medical Association; on the staffs of Sydenham Hospital and the Jewish Memorial Hospital, where he died April 12, aged 67, of acute myocardial infarction.

Scheele, Matthias Henry ⊕ University City, Mo.; St. Louis University School of Medicine, 1909; on the staff of Barnard Free Skin and Cancer Hospital in St. Louis; served as secretary and treasurer of the board of regents of Loras College in Dubuque, Iowa; died in St. Anthony's Hospital, St. Louis, April 2, aged 66, of cerebral hemorrhage.

Shelton, Hanson Penn, Georgetown, Ohio; Jefferson Medical College of Philadelphia, 1897; died in Good Samaritan Hospital, Cincinnati, April 24, aged 77, of acute coronary thrombosis.

Smith, Egbert Livingston ⊕ Waterbury, Conn.; Yale University School of Medicine, New Haven, 1896 served during World War I; an Associate Fellow of the American Medical Association; for many years affiliated with Waterbury Hospital; died April 20, aged 79, of coronary sclerosis.

Webb, Roy Abner, Pampa, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1916; member of the American Medical Association; past president of the Lions Club; died in Highland General Hospital April 19, aged 59, of cerebral hemorrhage.

Wisehart, William H., Colfax, Ind.; Central College *of Physi*cians and Surgeons, Indianapolis, 1897; member of *the American* Medical Association; died in Witham Hospital, *Lebanon*, recently, aged 87, of senility.

GOVERNMENT SERVICES

ARMY

Another Scrub Typhus Expedition to Malaya.—The Army Medical Service has again sent a team of scientists to the Federated Malay States and British North Borneo to make studies aimed at the eradication of scrub typhus from that area and other parts of the world. Scrub typhus proved almost as dangerous to American troops in the Pacific as the enemy during World War II. Knowledge acquired as the result of work done by three similar teams in Malaya during the postwar years has produced specific curatives. In 1948 such a team, after conducting experiments under controlled conditions, reported that some recently discovered antibiotics proved highly effective in the treatment of scrub typhus. Chloramphenicol (chloromycetin®), aureomycin, and terramycin, the drugs of choice in the order named, provide the only known specific treatment for the infection.

The mission of the present group is to attempt to develop an effective vaccine to prevent the initial infection and to experiment with impregnated clothing, chemical sprays, and other means of eliminating the mites that carry the disease. This group will undertake its studies at the invitation of the British and Malay governments. Headquarters will be established in the capital city of Kuala Lumpur, and the work will be carried on in collaboration with the British Scrub Typhus Commission, staff members of the Institute for Medical Research, and various Malayan medical groups.

The six officers making up the Army Medical Service team, all from the Graduate School Army Medical Center, Washington, D. C., are Maj. Charles L. Wisseman Jr., Maj. Herbert Ley Jr., and 1st Lt. Philip Y. Patterson, all officers in the Medical Corps; Capt. Warren G. Hoag, Veterinary Corps, and Maj. Robert Traub and 1st Lt. Fred Diercks, both of the Medical Service Corps. An additional member, Dr. David H. Johnson of the Smithsonian Institute, will leave the unit at British North Borneo to conduct studies of various jungle animals that serve as hosts for the infectious mites. The selection of this location was made necessary because of the hostility of Chinese Communist guerrillas who have made field work in the countryside and jungles of Malaya extremely hazardous. Dr. Johnson will be joined later by Major Traub, field director of the research team, and Major Wisseman after the Malayan program has been organized.

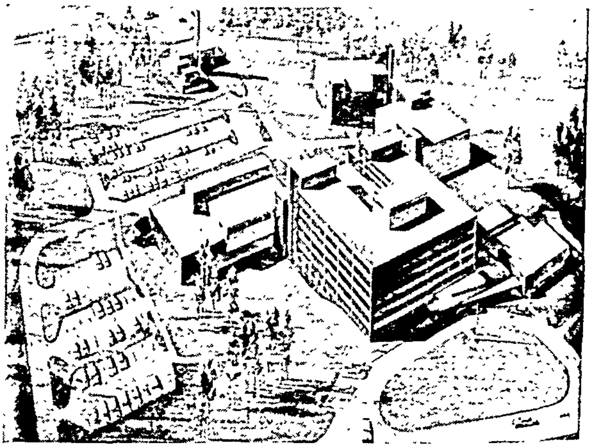
International Congress of Military Medicine. — Maj. Gen. George E. Armstrong, newly appointed Surgeon General of the Army, departed June 15 as an official delegate to the Thirteenth International Congress of Military Medicine and Pharmacy held in Paris June 17-23 under the sponsorship of the president of France. General Armstrong was joined in Paris by the other official Army delegate, Maj. Gen. Edgar Erskine Hume, chief surgeon of the Far East Command in Tokyo, who delivered and address on medical activities in Korea. Following these meetings, General Hume participated in the Fourteenth International Committee Meeting of the Congress at Vichy, France, June 24-25.

Medical Aspects of Nuclear Energy.—The Army's course in the medical aspects of nuclear energy will begin July 9 and continue throughout the week at the Army Medical Service Graduate School, Washington, D. C. Among the instructors will be Brig. Gen. James Cooney, radiation safety adviser during the recent atomic tests at Eniwetok; Brig. Gen. Elbert DeCoursey, director of the Armed Forces Institute of Pathology; Dr. Richard Gerstell, executive director of Civil Defense in Pennsylvania; Col. William Stone; Capt. Robert Hinners, USN, and Lt. Col. Joseph Cody, AF. Col. Roy Maxwell, chief of the biophysics department at the Army Medical Service Graduate School, is director of the course.

PUBLIC HEALTH SERVICE

New Building for Communicable Disease Center.—Plans have been completed for a new national headquarters building and research laboratory in Atlanta for the Communicable Disease Center of the Public Health Service. The new center, a group of six buildings to cost an estimated 12½ million dollars, will furnish facilities for a number of projects related to wartime protection of the civilian population as well as to peacetime public health. Projects closely connected with national defense include biological warfare defense studies and training, toxicological research on chemical warfare agents, and field training of certain military personnel in sanitation.

The center will be built next to the campus of Emory University, which donated the site, according to Dr. R. A. Vonderlehr, medical director. Additional Congressional authorization will be needed before construction can begin. Plans call for erection of: (1) the main building, consisting of a five-floor laboratory section, surrounded by an eight-story office section, (2) the infectious disease laboratory building of five floors, (3) the virus laboratory, also five floors, (4) the audio-visual production building, four floors, (5) the cafeteria, seating 135 persons, and auditorium, seating 300, and (6) the boiler house. All these buildings will be windowless, except for office space.



Proposed 12½ million dollar national headquarters building and research laboratory to be built at the Communicable Disease Center of the U. S. Public Health Center at Atlanta.

Defense-related activities of CDC include insect and rodent control operations around military and industrial establishments; biological laboratory research; training of personnel in the armed forces and civilian health establishments in sanitary methods; training for laboratory directors and technicians, and training of public health personnel from foreign countries.

The Communicable Disease Center, with a predecessor organization, has been located in Atlanta since 1942. Its normal peacetime duties are to assist the states in the prevention and control of communicable diseases, such as rabies, murine typhus fever, malaria, diarrheal disease, plague, and insect-borne encephalitis. Activities extend to every state and overseas territory. It has 500 employes locally, with more than 1,000 others throughout the United States. Headquarters temporarily are at 50 Seventh St., N. E., with principal laboratories at Chamblee, Ga., 14 miles from Atlanta.

When the new center is completed the virus laboratory will be moved to Atlanta from Montgomery, Ala. Earlier plans to bring the Technical Development Services of the Communicable Disease Center to Atlanta from Savannah have been cancelled because of the expense involved. That branch of CDC will remain in Savannah.

LONDON

Male and Female Death Rates.—Some interesting facts reviewed in an annotation in *Lancet* April 7, 1951, are based on a paper presented before the Royal Statistical Society on March 28, 1951, by Mr. W. J. Martin, D.Sc., of the Medical Research Council's statistical research unit. Martin reported that since death registration began, more than a hundred years ago, the ratio of male to female deaths has been consistently above unity in different age groups of the population and in different parts of the country. Furthermore, the female death rate is declining more quickly than the male, and the gap widens with increasing speed.

Although control of infection has produced a fall of about 50% in the death rate since 1870, the male death rate, which in 1841-1845 was 9.6% greater than the female death rate, became 27.6% higher than the latter in 1931-1935.

The actuarial expectation rose between 1840 and 1931 from 40.36 years to 58.74 in males and 42.04 to 62.88 years in females. Although much of the improvement was due to the eradication of childhood diseases, the male-female disparity was particularly remarkable at the age of 70—men had added only six weeks to their expected life span, while women gained some 16 months. Martin pointed out that, although men might claim to have borne the brunt of the occupational hazards of the industrial revolution, the present tendency for employment of women in industry has done nothing to stay the ever-increasing disparity in the death rates. It is true, however, that the adventurous spirit of the male makes him more liable to fatalities, even in childhood. Better home conditions may have lengthened the women's life span more so than their husbands', but industrial hazards for the latter have also decreased.

In the discussion of this paper, it was brought out that the excessive male death rate was a constant feature of the vital statistics of other parts of the world. Apparently, few animal studies have been made. Prof. A. Bradford Hill, president of the Statistical Society, recalled a study showing that the stillbirth rate was higher among male than among female calves. However, he said, further research on vital statistics of such domestic animals was complicated by the differential mortality effect of the economic end in view, that is, whether the animal was intended for meat or for milk. Comparative biology may provide an answer to the question of whether life for the male is short because it is hard or because of a deep-seated biologic inferiority.

Slimming by Television.—A leading article in the *British Medical Journal* of March 24, 1951, discusses a British Broadcasting Corporation television demonstration of the effects of a slimming diet on women volunteers. It is reported that more than 44,000 viewers have applied for the television diet sheet on slimming, which the British Broadcasting Corporation has promised to send its applicants. So far this diet sheet has not been made available. Although the corporation doubtless obtained the best medical advice for the experiment, the medical profession is concerned about whether the correction of a disorder of the body's metabolism is something that can safely be prescribed without medical supervision.

In a letter in the same issue of the *British Medical Journal*, the secretary of the British Dietetic Association points out that it is a principle of her profession "that no dietary advice should be given without specific instructions from the patient's doctor" and that "no printed diet sheet should be handed out without an interview during which the dietitian satisfies herself that the patient has understood the principle of the regime, and that it is within his or her means." This is one of the sensible regulations under which these highly qualified medical auxiliaries do their work.

Obesity if not a disease is certainly a departure from normal body health, and the treatment of such a condition by restriction of the diet to 1,000 calories a day in ignorance of the social and economic position of the 44,000 starvationists, and in particular in ignorance of any physical disorder that these obese sufferers may have, is a situation that the secretary of the British Dietetic Association is justified in describing as "potentially dangerous."

Dr. Stephen Taylor, a physician and medical journalist, is conducting a one-man campaign against fatness in the *News Chronicle*, a London daily paper. He writes: "There is one essential preliminary—a visit to your doctor"; one reason advanced for doing this is that the diet is low in vitamins A and D; hence vitamin supplements may be advisable. The doctor is thus being told in advance that a certain course of treatment has been prescribed and then is left with the invidious task of saying whether his patient should adopt a regimen that has been prescribed by somebody else. Furthermore, the Ministry of Health will have to consider whether the recommended vitamin supplements are to be regarded as medicines to be issued free of charge under the National Health Service or whether they should be regarded as a form of concentrated food suitable for those enjoying a certain diet. Although the *British Medical Journal* does not challenge the soundness of the advice of either Dr. Taylor or the British Broadcasting Corporation, it is suggested that the family doctors of Britain might not unreasonably complain at being asked to underwrite somebody else's dietetic policy.

Obesity is on the borderline between health and disease, and success of the British Broadcasting Corporation enterprise may encourage a further experiment which crosses the borderline.

DENMARK

New Headquarters of the Danish Medical Association.—Further data concerning the new headquarters of the Danish Medical Association, Domus Medica (*J. A. M. A.* 139:247 [Jan. 22] 1949), have now been published by Dr. Carl Mailand of Copenhagen. The original Domus Medica was destroyed in 1944 by the Germans, who believed that the doctors of Denmark must be warned and punished because of their underground activities. After the war, there was little prospect of rebuilding on the old site because of shortages of material and prohibitive costs. Early in 1948, when the situation seemed hopeless, a magnificent building became available. It was the Plessen Palace, which had been built in 1901 by Baron Josef v. Plessen, a man of great culture and wealth, at the cost of one million Danish kroner, an impressive figure at that time. The purchase sum in 1948 was one-and-a-half million Danish kroner, including the furniture and fittings.

There was, however, much to be done to convert this palace into a building fulfilling the requirements of a modern corporate body. To provide a lecture hall, two large rooms were made into one; even this arrangement provided seating accommodation for only 130 persons. It should, however, be possible to build a much larger room on the premises or elsewhere. The old Domus Medica was financed to some extent by rental of several of its rooms to outsiders on festive occasions. This source of revenue was never quite satisfactory, as the visitors could not help interfering with the daily routine of the owners. In the new Domus Medica, such hospitality on a commercial basis will be reduced to a minimum, although accommodations will be provided for corporate medical bodies wishing to entertain. About a dozen students, whose parents are doctors, are given residential accommodation in the building, which also houses the medical society and other medical associations. Certain rooms are named for doctors who have contributed 10,000 kroner each. The national medical associations of other countries have contributed generously to the equipment of the building. Its walls

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

and library are being refurnished, and the thousands of books destroyed in the library of the old Domus Medica are gradually being replaced.

Death of Dr. Otto Lassen.—Dr. Otto Lassen, who was born on March 17, 1881, and died on April 30, 1951, was a remarkable example of how much can be done without high academic rank. Early in his career he was put in charge of a tuberculosis station or dispensary in Aarhus. Here he was also in general practice. He soon became so engrossed in the many aspects of the tuberculosis campaign that this disease became and remained his chief interest. He was, in a certain sense, the father of the tuberculosis station system in Denmark, and his own station came to be the model for many others elsewhere in Denmark. It also became a teaching center, where many of his colleagues got their first training in tuberculosis work. He taught that the ideal tuberculosis station must have at its disposal a certain number of hospital beds to make it a complete unit. One of his many articles on tuberculosis, submitted to a medical journal for publication, was of such outstanding merit that he was urged to develop it as a doctorate thesis; he was 60 years old when he graduated as a doctor of medicine on this thesis. From his early days, before the stethoscope had been supplanted by radiological examination, until his death, he used to drive home certain elemental facts whose very simplicity tends to make them ignored. For example, he stressed the fundamental importance of the finding of tubercle bacilli whose persistent absence should be a check on the unwary diagnosis of active tuberculosis. He was in favor of letting women go to term when pregnancy was complicated by tuberculosis, being convinced that mother and child could come safely through the ordeal when well cared for. His impression of the merits of BCG vaccination was such that he gradually extended the indications for this measure, which he at first confined to persons born into a tuberculous environment, nurses, and medical students. Later he advocated such vaccination for both children and adults if they were Mantoux-negative. *Ugeskrift for Laeger* published at the time of his 70th birthday a series of articles on tuberculosis, many of them written by his old pupils. What touched him greatly on this occasion was the request by his hospital committee that he should continue to hold his hospital appointments despite his having reached the age limit. Death occurred, presumably as the result of coronary thrombosis, only a few weeks after he had celebrated his 70th birthday.

MEXICO

Contributions of the Instituto Nacional de Cardiología.—Productive investigations in several fields have been conducted recently at the Instituto Nacional de Cardiología.

Pharmacology.—A digitalis-like substance, thevetoidin, has been isolated from a Mexican species of Thevetia (Thevetia gaumeri). Thevetoidin is a mixture of crystalline substances containing two types of polysaccharides, a small amount of a quaternary ammonium base and a pure glycoside, which is in the process of being identified. Thevetoidin has a rapid action, similar to that of strophanthin.

Physiology.—A new method has been developed for the study of coronary flow in the isolated heart which permits more accurate analysis of the factors that determine coronary output.

Electrocardiography.—Institute workers for the first time have recorded the electrical phenomena within the mass of the septal wall, not merely septal surface phenomena. This has been effected by the use of simultaneously recovering electrodes placed at various depths within the septum. This method has revealed a septal activation different in many respects from previous concepts.

Hemodynamics.—In December, 1948, for the first time, the institute hemodynamics team introduced a catheter through the patent ductus to the aorta from the pulmonary artery. Forty such catheterizations have been performed successfully.

CORRESPONDENCE

DEATH FOLLOWING CURARE ADMINISTRATION

To the Editor:—In view of the recent report by Foregger, "Fatalities Following Curare" (*J. A. M. A.* **142**:1344 [April 29] 1950), I felt it would be timely and valuable to report a case of prolonged apnea and death following anesthesia supplemented with curare and syncurine® (decamethylene-1,10-bistrimethylammonium dibromide).

On Feb. 13, 1950, a photographer, 53, underwent a gastric resection for duodenal ulcer. Other than the main complaint of obstruction and previous bleeding, there was nothing in this patient's history pertinent to this problem. There was no history suggestive of myasthenia gravis. Examination of the heart and lungs and chest x-ray disclosed no abnormalities. Premedication consisted of 1 mg. of dihydromorphinone hydrochloride and 0.40 mg. of atropine, given one hour before anesthesia was begun.

The operation proceeded with somewhat greater than average difficulty, taking three hours and ten minutes. During this time, the blood pressure was well sustained except for a short interval when the duodenal stump was being manipulated, when the blood pressure fell to 100/64. The anesthetic agent was nitrous oxide-oxygen-ether (not endotracheal). The patient received a total of 4 cc. (3 mg. per cubic centimeter) of *d*-tubocurarine and 5 mg. of syncurine.® No *d*-tubocurarine was given during the last hour and a half of the operation; the final dose of syncurine® was 1 mg., given for the closure of the peritoneum and fascia. The patient at all times was well oxygenated and had no respiratory difficulty. As the closure was being completed, it was noted that the patient's respirations were becoming more and more shallow and finally ceased. During the following seven hours, the patient was intubated and was artificially ventilated. In an early effort to stimulate the carotid body mechanism, mild cyanosis was allowed to prevail. In subsequent hours, the following drugs were administered: nikethamide (coramine®), caffeine, phenylephrine hydrochloride, and picrotoxin. Procaine and the antihistaminics were not used. Admixture of room air and ether vapor had no visible effect.

Throughout the operation and the postoperative hours of apnea, the patient received a total of 1,000 cc. of blood and 1,000 cc. of 5% dextrose in isotonic sodium chloride solution. At no time did there seem to be respiratory obstruction. The patient could always be ventilated easily. Indeed, it was surprising at times to see how pink the patient's color remained, even though ventilation was not performed manually, sometimes for minutes at a time. About four hours after the period of apnea had begun, the patient's blood pressure began to fall and his pulse to accelerate and his pupils became dilated and unresponsive to light. The administration of phenylephrine hydrochloride corrected the blood pressure and pulse abnormalities; however, the pupillary dilatation persisted. It was felt at this time that, even if recovery should occur, irreversible cerebral damage had taken place.

The patient's pharynx and tracheobronchial tree were aspirated as indicated, although at no time was there an unusual amount of mucus or moisture. Five hours after the period of apnea had begun, the patient was placed in a respirator, with the endotracheal tube in place and a catheter delivering oxygen to the patient through the endotracheal tube. About two hours later, the patient made efforts to reject the endotracheal tube; as it was removed the patient died. A Levine tube was in place throughout this entire period.

This case suggests the existence of a medullary side effect of *d*-tubocurarine and/or syncurine® which cannot as yet be anticipated and for which no effective therapy is available.

ERRORS IN BOOK REVIEW

To the Editor:—I would like to point out some serious errors made in the review of my book "Physicians' and Nurses' Concise Medical Encyclopedia" in THE JOURNAL of Nov. 4, 1950. 1. Your reviewer condemned the book because he found a misspelling of "Gaffky" (a typographical error) and assumed that my spelling was poor. However, on page 98, under a leading article, "Gaffky" is spelled correctly. 2. Your reviewer quoted the first sentence of my article on "pulmonary embolism" as evidence that I did not know the etiology of the disease. The etiology, however, is given in the second sentence of the article.

WILLIAM H. KUPPER, M.D., Beverly Hills, Calif.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The following special report submitted by the Council to the House of Delegates and approved by that body at the annual meeting, June, 1951, is being printed in full because of the numerous requests received by the Council for information on this subject. DONALD G. ANDERSON, M.D., *Secretary.*

POLICY OF THE AMERICAN MEDICAL ASSOCIATION REGARDING THE PRODUCTION OF PHYSICIANS

Discussions of the supply of physicians in the United States in recent years have sometimes implied that the American Medical Association, through its Council on Medical Education and Hospitals, seeks to limit the supply of physicians in this country by limiting the number of medical schools it approves, by curtailing enrolments in schools it approves, or by otherwise preventing expansion of the nation's facilities for the training of physicians. It is important that there be a clear understanding of the policies of the American Medical Association in this area.

The American Medical Association has no desire to limit the production of properly trained physicians to serve the American people. The policy of the Association is to assist and encourage any responsible group or institution endeavoring to create new facilities or expand existing facilities for the training of physicians.

The number of medical schools approved is determined entirely by the ability of schools to meet acceptable educational standards. All medical schools in operation in the United States at present are fully approved by the American Medical Association.

The Association does not attempt to regulate the size of the national student body in medicine. The number of students admitted to individual schools is determined by the faculties, administrative officers and governing boards of each school, in accordance with the school's educational philosophy and its own judgment of its educational resources. In order to preserve high educational standards, the American Medical Association may advise a school to reduce its enrolment only when there has been an enrolment increase considerably in excess of increases in facilities.

The number of medical students in approved schools has been steadily increasing. In 1910 there were 12,530 students in approved schools; today there are more than 26,000. In the last 10 years the number of medical students has increased by almost 5,000. This is the equivalent of creating at least 15 new medical schools of average size. The American Medical Association has lent every aid and encouragement to this sound expansion. In many states the medical societies have provided effective leadership in the establishment of new medical schools and the expansion of existing schools.

Still further increases in the production of physicians are in prospect. The present freshman class numbers more than 7,100 students, the largest on record. It is 23% larger than the freshman class entering medical schools in 1940. During this period the general population increase in this country was 14%. In fact, physicians have increased in numbers more rapidly than has the population at large, for more than 20 years.

It is probable that the freshman medical class will number 7,500 or more within a year or two and that by 1960 the production of physicians will be at least 30% greater than in 1950, a rate of expansion that promises to exceed that of any other major profession, and will greatly exceed the general population increase.

The American Medical Association has also facilitated the entrance into practice in this country of physicians educated abroad. After due study, it has recommended to state licensing boards that the graduates of 48 foreign medical schools be accorded the same opportunities for licensure as graduates of approved medical schools in the United States. This liberal policy in itself should make it clear that the Association is not attempting for selfish reasons to limit the number of physicians practicing in the United States.

The American Medical Association is duty bound to protest exaggerated estimates of the need for additional physicians that can only be met by debasing the quality of medical education. It would be derelict in its responsibility to the American public if it failed to make clear that a deterioration in the quality of medical care is an inevitable consequence of lowered standards of medical education.

In the past half-century the American Medical Association's efforts to improve medical education have been a major factor in the greatly improved health of the American people. For the future, the Association pledges its every effort to maintain high standards and to support expanding programs of medical education to the end that the American people may continue to enjoy the benefits of medical care unsurpassed in quality and quantity anywhere on earth.

ESTABLISHMENT OF A QUOTA BASIS FOR THE APPOINTMENT OF INTERNS

At its meeting June 8-9, 1951, the Council on Medical Education and Hospitals approved the following statement of policy regarding the approval of hospitals for intern training.

DONALD G. ANDERSON, M.D., *Secretary.*

Since 1914, the Council on Medical Education and Hospitals of the American Medical Association has approved hospitals for the training of interns without specifying the number of interns that could be accepted under the program as approved. Until recent years, this policy created no problem since the number of internships offered and the number of applicants were approximately equal.

During the past 10 years however, the number of internships offered in approved hospitals has steadily increased to the point where it is estimated that there are now at least 3,000 more internship appointments available than there are applicants to fill them. This disparity has produced a number of undesirable effects. Hospitals, large and small with few exceptions, have been unable to assure themselves of a definite number of interns from year to year and have thus been handicapped in developing stable educational programs. Applicants not infrequently have been subjected to undue pressure in making decisions with respect to hospital appointments. Some hospitals in competing for interns have stressed factors other than those of an educational nature; still others have offered an excessive number of appointments, which when filled have resulted in overstaffing with a consequent deterioration of the quality of training provided.

To ameliorate this situation, the Council hereafter, when approving hospitals for intern training, will specify the number of internships for which a hospital is approved. The first list of hospitals approved on this basis will appear in the 1951 Internship and Residency Number of THE JOURNAL, scheduled for publication Sept. 29, 1951. As a basis for computing the quota for hospitals approved prior to April 15, 1950, the following formula will be used:

1. Hospitals approved for intern training only: In these hospitals, the number of internships to be offered for the period July 1, 1952-June 30, 1953, will be limited to 80% of the num-

ber offered in 1950 as listed in the 1950 Internship and Residency Number,[1] or to the total number offered in 1940, whichever is the larger.[2]

2. Hospitals approved for intern and residency training: In these hospitals, the number of internships to be offered for the period July 1, 1952-June 30, 1953, will be limited to 70% of the number offered in 1950 as listed in the 1950 Internship and Residency Number or to the total number offered in 1940, whichever is the larger.[2]

A similar quota based on comparable bed capacities and annual admission rates will be allocated to hospitals approved since the publication of the 1950 Internship and Residency Number. In no instance will the number of appointments in a hospital offering a rotating type of internship be reduced to less than four.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Building Restrictions: Right of Chiropractor to Maintain Office in Home.—The plaintiffs filed a suit for an injunction against the defendant chiropractor to restrain him from conducting or engaging in any business or profession in his private home. From a judgment of the trial court granting the requested injunction, the defendant appealed to the Court of Appeals of Maryland.

In 1942 the defendant acquired some real estate on Terrace Street in the Northern Heights Addition to the city of Hagerstown, Md., and constructed thereon a house that cost approximately $40,000. The deed conveying this property contained a building restriction providing, among other things, that "the said premises shall be occupied and used for residence purposes only and not otherwise." The plaintiff's bill alleged that the defendant plans to engage in the business of practicing the profession of chiropractic in the basement of this building and that he had informed one of the plaintiffs that he intends to occupy the building as a residence and also conduct his office and practice his profession as a chiropractor in said building. In his answer the defendant denied he had expressed himself as intending to conduct his office and professional practice exclusively in his residence but averred that he proposed only an incidental use of the said residence for professional office purposes, such use being supplemental, beyond usual office hours, to his regular office which is maintained in another location. The defendant admitted a desire to save office rent but refused to commit himself to any plans for the near or distant future. He did testify, however, that he intends to perform, at his residence, his duties as secretary of the Board of Chiropractic Examiners. The trial court refused to recognize any distinction between practice of a profession wholly at or from one's residence and "incidental" practice to a limited extent in special circumstances, but construed the covenant that the premises "shall be occupied and used for residence purposes only and not otherwise" as prohibiting conducting or engaging in any business or profession on the premises. The trial court therefore granted an injunction in the broadest terms, in the words of the covenant plus this implied prohibition, without any definition or limitation of "use for residence purposes only" or "engaging in any business or profession."

The narrower definition of "residence purposes only," which is reflected in the trial court's decree, was well expressed in a case in a Pennsylvania lower court decision: "Use as a private dwelling house means use by way of living, eating, sleeping and enjoying the various intellectual and social diversions incident to private family life. The practice of a profession, however, is, in part at least, for the purpose of gain. It is similar in that respect to the carrying on of a business or trade. It is no answer to say that doctors, lawyers and dentists frequently conduct their offices in their homes. To the extent to which they do this (at least habitually, regularly and continually), they are using part of their dwelling houses for other than dwelling house purposes." This definition, said the Court of Appeals, which comprises little more than "eat, drink and be merry," is too narrow. School children and undergraduate and graduate students are not the only persons who do "home work" in a house used "for residence purposes only." Even children may be actuated by a hope of future gain as well as an abstract love of learning. Most people at home occasionally think and read, frequently talk, and not infrequently "talk shop." We cannot say that when one is reading Aristotle or Shakespeare or Dickens or "Gone with the Wind," or a physician is talking politics or a politician is discussing medicine, he is within his rights, but when he is reading law or medicine or Dale Carnegie or a physician is talking medicine or a politician talking politics, he is violating a restrictive covenant. All the work of a particular gainful calling may be home work, incidental to the use of premises "for residence purposes only," e. g., Trolloppe's self-imposed allotments of daily work on his novels. In this respect we see no difference between Ogden Nash's published verses (if written at home) and verses written by members of a literary club for their mutual enjoyment or by an individual for Christmas cards for his friends. If, however, a novelist or other author works with a staff of secretaries, proof-readers or other assistants, such work would not be consistent with use of the premises for residence purposes only. Such activities might constitute use for both residence and business purposes, or for business with incidental residence use like the use of chambers in one of the Inns of Court by a barrister who resides at his chambers.

The lower court expressed the opinion that the weight of authority supports the conclusion that property restricted exclusively for residence purposes cannot be used as contemplated by the defendant. Does any use of the dwelling house for the purpose of conducting a real estate and insurance business therein, as a matter of law, destroy its character as a private dwelling house? The suggestion has been made in judicial opinions that some kinds of personal business, such as that of a physician or a lawyer, may be carried on in one's dwelling house without inconvenience to the neighboring property holders and without changing the general private character of the use of the building. Doubtless this may become a matter of degree, so that we refrain from holding that the complaint does not state a cause of action, but it does not follow that if a physician sees his patients or a lawyer meets his clients at his house in a room which he calls his office, he thereby destroys the character of his home as a private dwelling house in the usual meaning given to such words.

As there is at least a doubt that the practice of medicine is prohibited, we must hold that it is not prohibited. If the practice of medicine is not prohibited, it does not follow that any and all practice is permitted. Before and since 1910 some physicians so constructed or altered their houses that architecturally their offices were offices and were distinct from, though connected with, their residences. Such buildings would not be permitted by the covenants now before us. It is undisputed that defendant's house is architecturally one of the best residential types. Many physicians now maintain offices, very different from most physicians' offices in 1910, with laboratories, various instruments and other facilities, associate physicians, secretaries, nurses, technicians or some such facilities or assistants or both. Such offices would not be permitted by these covenants. As usual, the line can only be drawn case by case. Defendant's testimony indicates, not very clearly, that for what he calls incidental use of his residence the only equipment he would locate in the house would be "an adjusting table in the basement, the same as I had out at my home for my family, [and] any of the low voltage currents which are portable, the same as you would use for a house call." There is an outside entrance to the basement, and the basement, if not so used or put to some special use, e. g., as a billiard room or a children's play room, might not be used at all or might be put only to the miscellaneous uses of an unfinished cellar. We do not think such incidental use of the basement would impair the use of the house "for residence purposes only", concluded the Court of Appeals. If defendant should abandon his present office and remove it to his residence, there is not sufficient evidence as to how the present office is conducted, to enable us to determine whether or not such an office at the residence would violate the covenants. Our decision will be without prejudice to further proceedings in this case or a new case, if and when such a change is made or threatened and plaintiffs are in a position to show the material facts. Defendant should not be permitted to *maintain* a professional or business sign on his residence. A sign is a business use of property, separable from residential use and also from incidental use in practice of a calling, and is therefore prohibited by these covenants. Defendant proposes to keep in the basement five filing cabinets and other files relating to his duties as secretary of the Board of Chiropractic Examiners and to perform his duties there. We see nothing in the covenants to prevent a physician or a lawyer or the Secretary of Medical Examiners, Bar Examiners, or Chiropractic Examiners from doing his "paper work" at home, including attention to correspondence or preparation or marking of examination papers. Defendant, however, says that at certain times "there are many, many candidates coming and getting applications, some by writing and some by personal appearance." Maintenance of such a public office to receive so much of the public as may have occasion to come in, is just as clearly a violation of the covenants as maintenance of a marriage license bureau would be. Accordingly the decree in favor of the plaintiff was reversed and the trial court was ordered to enter a decree in accordance with the opinion of the Court of Appeals.—*Osborne v. Talbot, 78 A. (2d) 205 (Maryland 1951).*

---

[1] J. A. M. A. 142: 1149 (April 15) 1950.

[2] Appropriate adjustments of these quotas may be made on request by the hospital in those instances in which bed capacities have been increased since 1950 or in which additional hospital services are presently being provided.

Admissibility in Evidence of Results of Chemical Tests for Intoxication.—The defendant was convicted of driving a motor vehicle while intoxicated. From such convinction he appealed to the court of criminal appeals of Texas.

The defendant admitted that he drove the vehicle at the time alleged but denied that he was intoxicated. He did, however, admit drinking four bottles of beer in the late afternoon and evening before his arrest. When taken to the City Hall by the police, the defendant signed a written permission for the officers to test his breath for alcohol by an instrument known as the Harger Drunkometer. The officers who arrested him and observed him after his arrest gave ample evidence to sustain the jury's verdict independent of the results of the chemical test, the court indicated. In addition to the testimony of the officers, however, Dr. Beerstecher, a research biochemist at the University of Texas, testified in part: "I am familiar with the instrument known as the Harger breath test; I have been studying that between ten and eleven months. I feel that the machine is extremely reliable. It shows how much alcohol is in a person's blood at the time the test was taken." On cross-examination, this witness stated: "There is disagreement among scientists as to the accuracy of the (Harger) breath test. A chemical analysis of the blood itself shows what per cent or proportion of alcohol is in that blood sample. The theory of the (Harger) breath test is that the breath indicates a per cent of saturation in the blood; it is a calculated proportion. This breath test is used in a number of states. From my work with this machine for some ten or eleven months, observing the officers making the tests, and from my knowledge as an expert on alcohol, my opinion is that the (Harger) machine is very reliable."

The chief contention made by the defendant, said the court of appeals, is that it was prejudicial error for the trial court to permit the State to introduce evidence of an alcohol breath test of the defendant and the results purportedly shown thereby because the State did not prove that such breath-test and its results are generally accepted by scientists as accurately establishing the alcoholic content of a subject's blood to show whether he was under the influence of intoxicating liquor and the extent of his intoxication. The objection, said court, is to the conclusion reached because Dr. Beerstecher, after qualifying as an expert witness, stated that there was a difference of opinion among scientists as to its accuracy. The position that it is incumbent upon the State in the trial of the case to prove that the test is scientifically accepted, said the court, may or may not be correct, depending upon the degree to which the fact is established by scientific research. This court may recognize generally accepted scientific conclusions, even though there should be some who disagree with them. In all probability a scientist may be found who will disagree with practically every generally accepted scientific theory. The opinion of such others by no means bars the evidence of a scientific truth before a jury, nor would it preclude the courts from taking judicial knowledge of the truth of it. Continuing, the court said that Northwestern University of Evanston, Illinois, has within the present year, 1950, published a work from which the court quoted. "Medical science, through years of research and experimentation, has established that it is not the amount of alcohol consumed by a person that affects his driving ability but the amount of alcohol absorbed into his blood, and thus circulated to the brain, that affects his nerves and, correspondingly, his mental and physical faculties. . . . The most commonly used methods of determining a person's blood alcohol concentration is to chemically analyze the blood, urine, or breath. The amount of alcohol in the latter two substances directly parallels the amount of alcohol in the blood and, therefore, from the amount of alcohol excreated through the kidneys or lungs, the concentration of alcohol in the circulating blood can be determined accurately and scientifically." When supported by such authorities, said the court, this proposal is persuasive in supporting the evidence of Dr. Beerstecher, if that evidence needs to be supported, as to the effect of alcohol in the blood. Dr. Beerstecher testified that the instrument in question is accurate and he gave his reasons for it. He admitted that there are others who disagree with its accuracy. The objection to his testimony, therefore, goes to its weight and not to its admissibility. Our conclusion, said the court, is that this evidence is admissible as presented to us in this record for whatever it is worth, and it was not reversible error to overrule the defendant's objection to it. Accordingly the defendant's conviction was sustained.—*McKay v. State, 235 S.W. (2d) 173 (Texas 1951).*

MEDICAL MOTION PICTURES

Rodney: 16 mm., color, sound, showing time 11 min. Produced in 1950 for the National Tuberculosis Association by Film Graphics, Inc., New York. Procurable on loan from local tuberculosis associations.

This motion picture deals entertainingly with the serious problem of tuberculosis control. The central figure is Rodney, a breezy caricature of typical American youth. During a routine physical checkup, the doctor discovers that Rodney has early tuberculosis; through his answers to Rodney's questions, he provides information about the spread, treatment, and cure of tuberculosis. These answers contain many positive statements that serve to correct misconceptions. Points that are strongly stressed are the importance of rest in tuberculosis, the importance of the tuberculosis hospital as the place for treatment, and the importance of the chest x-ray as a means of discovering tuberculosis in its early stage.

The producer indicates that the film is intended for high school and college students and that the discussion leader has an extremely important role to play at every showing. In the opinion of the reviewers, these are very important points. Guides for discussion leaders are available from the producer. The material presented is medically correct. However, the entertainment value appears at times to be greater than the teaching value. It is recommended for use mainly with high school students, as an introduction to a more detailed discussion of the subject. The photography and sound are excellent.

SELECTED FILMS FOR HOSPITAL ADMINISTRATION

The University Hospitals, State University of Iowa, have prepared a 32 page pamphlet listing 318 selected films of interest to hospital administrators and teachers of hospital administration. Copies of the pamphlet may be obtained from the Committee on Medical Motion Pictures of the American Medical Association or from the Extension Division, State University of Iowa, Iowa City.

Staphylococcic Infections in Hospital Nurseries and Pediatrics Wards. J. Felsen, J. Lapin, W. Wolarsky and others.—p. 534

Simplified Transparent Tuberculin Patch Test. H. Vollmer and D. R. Lyons.—p. 541.

Congenital Pulmonary Stenosis.—Leininger and his associates review the first 214 cases in which a Blalock or Potts-Smith procedure was attempted at Children's Memorial Hospital, Chicago. The preoperative diagnosis was tetralogy of Fallot in 199 cases and tricuspid atresia in 15. An anastomosis was performed in 199 patients. Eighteen children (9%) died in the immediate postoperative period; one child died in an automobile accident three months after operation, and 35 children were not seen after surgery. The remaining 145 patients were observed for postoperative periods ranging from six to 42 months. Paroxysmal dyspnea, which occurred in 66 children prior to surgery, was not observed in any patient postoperatively. The average preoperative values for red blood cell count and hemoglobin level were 6,930,000 per cubic millimeter and 18.3 gm. per 100 cc. respectively; the average postoperative values were 5,350,000 per cubic millimeter and 14.4 gm. per 100 cc. The decrease in cyanosis following surgery was usually immediate and pronounced, and, in the majority of cases, this improvement remained essentially unchanged throughout the period of observation. The decrease in the clubbing of the fingers and toes was fairly complete by the end of the first year. The increase in exercise tolerance was encouraging in all cases and dramatic in a few. The heart enlarged to some degree after surgery in all cases. Minimal (5 to 10%) cardiac enlargement occurred in seven patients, in spite of excellent improvement in cyanosis and exercise tolerance following surgery. Most of the patients showed mild (15 to 35%) cardiac enlargement, which usually occurred within the first six months after surgery. Seven showed severe (85 to 180%) cardiac enlargement with chronic heart failure requiring digitalis therapy. In each of these cases, unusual cardiac enlargement was apparent within six months after surgery and there was no significant increase after 12 months. Four of these showed symptomatic improvement and decreased cyanosis in spite of marked cardiac enlargement. One patient died 11 months after surgery and four months after digitalis medication was started; another was given digitalis therapy four months after surgery and died seven months postoperatively. Postmortem examination revealed similar findings in each case; a tetralogy of Fallot with a partly overriding aorta was present. Two other patients in this series manifested cardiac failure with severe enlargement of the heart. Five patients in addition to those described above died during the three-and-one-half year period of observation. Autopsy in two of the cases revealed transposition of the great vessels in addition to pulmonary stenosis. It was concluded that the Blalock or Potts-Smith procedure alleviates the symptoms occurring in certain types of congenital pulmonary stenosis.

Pathogenesis of Periarteritis Nodosa; Occurrence in Association with Glomerulonephritis.—The histories of two patients with periarteritis nodosa are presented. Both patients had glomerulonephritis. It is suggested that the periarteritis was due to: (1) the same pathogenic process that was responsible for the glomerulonephritis; (2) hypertension, or (3) a sulfonamide compound and was an allergic reaction. Studies and observations on these patients do not permit the conclusion that the periarteritis nodosa was due specifically to the operation of any one of the suggested mechanisms. One of the two cases is the second on record in which periarteritic lesions occurred exclusively in the lungs.

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Chick Embryo Method of Preparing Smallpox Vaccine.—A new method for the preparation of smallpox vaccine became available with the successful propagation of vaccinia virus in the chorioallantois of the developing chick embryo. It is felt that the chick embryo may be safely substituted for the calf as a source for vaccine. Studies on the behavior of vaccinia virus in the chick embryo revealed the following points: 1. The best source for chick embryo-propagated smallpox vaccine is the 36 to 48 hour membranal lesions obtained by carefully titrated inoculation of the 11 or 12 day chorioallantois. 2. A vaccine with the qualities of potent calf lymph can be prepared in quantity from the first passage in the chorioallantois. 3. Buffer saline serum is a superior protective diluent for smallpox vaccine prepared by the chick embryo method. 4. Smallpox vaccines prepared as 1-in-50 suspensions in buffer saline serum have keeping qualities superior to those prepared as 1-in-10 or 1-in-15 suspensions. The 1-in-50 suspensions meet the required standard potency titration tests after at least one year of storage at 0 to 5 C.

Pulmonary Embolism—Present Status. W. F. Renner.—p. 266.

Stellate Ganglion Block in Cerebral Thrombosis.—The rationale for the use of stellate ganglion block in the treatment of cerebral thrombosis is that it causes dilatation of the cerebral vessels, thereby limiting the vasospasm and subsequent anoxic damage that usually follows occlusion of a cerebral vessel by a thrombus or embolus. Stellate ganglion block was done on alternate patients with a clinical diagnosis of cerebral thrombosis or embolism admitted to the medical service of the Jersey City Medical Center. Twenty patients had stellate ganglion block, and 22 patients served as controls. The anterolateral approach and the infiltration and diffusion technique were used, so that the middle cervical ganglion was also blocked. A total of 56 blocks were performed. The procedure was repeated daily, until there was no further evidence of improvement or until the patient's symptoms cleared. Forty-five per cent of the controls died, but only 30% of those receiving stellate ganglion block died. Many patients noted varying degrees of improvement immediately following the block. One patient died as the result of the stellate ganglion block. A thorough knowledge of the anatomy of the region and a careful technique are required, so that such serious accidents may be avoided.

Prevention of Thromboembolism.—The authors believe that the frequency of thromboembolic disease in both medical and surgical patients warrants the adoption of broad prophylactic measures to reduce this incidence. In preoperative surgical patients the following procedures should be done routinely: reduction of weight in the presence of obesity, correction of varicose veins if feasible, medical supervision of cardiac abnormalities, correction of anemia, and administration of a diet with high carbohydrate and vitamin content. Recommended postoperative prophylactic measures include early ambulation, leg exercises in bed, avoidance of compression of calf veins, use of elastic stockings in those with varicose veins, and use of anticoagulant drugs. Of these, repository heparin is the most suitable because of its simplicity of administration, rapid and prolonged effect, wide margin of safety, and requirement of minimal laboratory control. Prophylactic vein ligation should be reserved for patients in whom anticoagulants might aggravate a bleeding tendency, and for chronically bed-fast patients who have thromboembolic potentialities. The entire program of postoperative prophylaxis should be applied to all patients who (1) have a history of thromboembolic or occlusive arterial disease, (2) are in cardiac failure, (3) have large hearts or auricular fibrillation, (4) are obese, debilitated, polycythemic, or anemic, and (5) are over 50 and have no specific contraindication to anticoagulant administration. For the majority of normal patients below the age of 50 prophylaxis can be withheld unless periodic examination of the lower extremities reveals early phlebothrombosis. The authors report a decrease in the incidence of thrombosis and pulmonary embolism in a series of 102 postoperative patients receiving prophylactic anticoagulant therapy as contrasted with 102 control postoperative patients. They outline specific prophylactic programs for postpartum and orthopedic patients and for those with myocardial infarction, auricular thrombus and embolization, or recurrent idiopathic thromboembolism. In addition, they suggest that repository heparin may be useful in the therapy of thromboangiitis obliterans, diabetic atherosclerosis, endarteritis obliterans, and frostbite.

Antibiotics in Staphylococcic Endocarditis.—Eighteen patients with staphylococcic endocarditis were observed over a three year period. In nine of the cases the etiological organism was Staphylococcus aureus, and in the remaining nine it was Staphylococcus albus. Twelve patients died, six in each etiological group. Of those with Staphylococcus aureus endocarditis who survived, only one responded to 20,000,000 units of penicillin daily. The other two responded dramatically to aureomycin given in a dose of 1 gm. every four hours. Two of the three surviving patients with Staphylococcus albus endocarditis responded to penicillin. In the third patient the organism was resistant to penicillin but relatively sensitive to aureomycin. Therapy consisted of penicillin in a dose of 2,000,000 units every three hours intramuscularly and 1 gm. of aureomycin every six hours. Within 24 hours after beginning of the therapy the temperature was restored to normal. In vitro bacterial sensitivity studies were done in 15 of the 18 patients. In 10, the organism was relatively resistant to penicillin. The infecting agent showed aureomycin sensitivity in three of four cases in which the organism was penicillin-fast. In one patient increasing resistance to aureomycin developed during therapy. Intially 5 γ of aureomycin per cubic centimeter of culture were required for in vitro inhibition. At the end of 10 days of aureomycin therapy, the amount necessary had increased to 40 γ. Results of sensitivity studies and therapeutic response reported suggested that aureomycin may be effective when bacterial resistance to penicillin is observed. Staphylococcic resistance to aureomycin may develop.

Vestibular Function Following Streptomycin Toxemia.—Of 62 patients with pulmonary tuberculosis who were given 2 gm. of streptomycin daily for an average of 110 days, 42 had complete loss of vestibular response to caloric stimulation. In the great majority of cases, response returned in varying degrees over a period of two years. More patients weighing less than 125 pounds (56.7 kg.) lost response than did heavier patients, and the rate of loss was also higher among patients aged over 45. Response returned earlier in the younger patients than in the older. Of 215 patients with pulmonary tuberculosis who were given 1 gm. of streptomycin daily for an average of 110 days, 18 had complete loss of vestibular response to caloric stimulation. Sixteen regained response within a year, one in 17 months and one was lost to study.

Natural History of Acute Leukemia.—A study was made of 114 male patients and 58 female patients with acute leukemia. The patients were between the ages of 2 months and 73 years and were seen at Memorial Hospital, New York, from 1926 through 1948. Twenty-two of these patients were admitted after May 1948 and were treated with pteroylglutamic acid (folic acid) antagonists. They were excluded from the total group of 172 patients for computation of survival times and remissions but were included in all other analyses. Symptoms, signs, and hematological data were briefly considered. It was found that 8.7% of the 150 patients had some degree of temporary remission but that only 4% had complete temporary remissions. No patient in this group had more than a single remission. Remissions appeared unrelated to type of preceding treatment or to infection. Mean survival time from the onset of symptoms was 20.3 weeks. The longest survival was 58 weeks, but 50% of the patients were dead by 17 weeks and 90% by 36 weeks. Roentgen therapy, nitrogen mustards, radioactive phosphorus, and urethane were all without significant therapeutic effect. Improved supportive measures, such as antibiotics and generous use of blood transfusions, appear to have caused a slight but significant increase in survival time. Sixteen illustrative cases are reported in detail.

Cytological Diagnosis of Breast Cancer with Paget's Disease.—The occurrence of intraductal cancer of the breast associated with beginning Paget's disease of the nipple in a woman aged 41 is reported. There were no palpable masses in the breast. The intraductal mammary cancer was not clinically detectable by the usual means, and the diagnosis of the neoplasm was first established by cytological examination of smears made from a discharge collected from the mouth of the lactiferous duct. The smears were prepared according to Papanicolaou's technique, and cancer cells were identified in the material. Intermittent discharge from the nipple, the symptom of the intramammary lesion, preceded by six months the appearance of an erosion of the apex of the nipple, a biopsy of which revealed the characteristic evidence of Paget's disease. This sequence lends additional support to the view that Paget's disease of the nipple is secondary to intramammary carcinoma.

Emotion and Circulation. M. D. Altschule.—p. 444.

Acute Nonspecific Pericarditis.—Thirty-five male and 15 female patients between the ages of 10 and 70 with acute nonspecific pericarditis are reported on. Forty-five of these patients were followed up for two to 18 years. The commonest presenting complaint was pain generalized over the entire anterior chest or limited to certain areas of the chest. The variable nature of the pain and the difficulty of differentiating it from the pain of other cardiac and pulmonary diseases was apparent. Malaise, fever, cough, and dyspnea were the commonest accompanying complaints. A pericardial friction rub, the physical finding of greatest significance in the diagnosis of this disease, was heard in 37 patients. Enlargement of the cardiac shadow was observed in 25 instances, and pleural fluid was also noted in 14 instances. Follow-up examination showed that in general the majority of the patients were in excellent health. Six patients had recurrences, and a recurrence was suspected in three additional patients. In general, recurrences were of less intensity and of shorter duration than the initial illness. One patient died of chronic hypertensive cardiovascular disease, which had been present for years prior to the episode of acute pericarditis. Despite the excellent prognosis indicated by the results of the follow-up examinations, residual significant electrocardiographic abnormalities were observed in six patients. Of 37 patients of whom x-ray follow-up examination was made, three had left ventricular enlargement and six had prominent left ventricle without cardiac enlargement. There was pericardial calcification in only one patient, and fluoroscopy revealed a diminution in the amplitude of cardiac contraction, but there was no evidence of impaired function. The prevailing theories of causation of acute nonspecific pericarditis include virus or tuberculous infection of the pericardium and pericardial response to unknown toxins or hypertension.

Choline and Experimental Canine Arteriosclerosis.—Studies were made on the possible therapeutic effect of large amounts of dietary choline on arteriosclerosis produced in dogs by a regimen of cholesterol and thiouracil feeding. Three dogs were used for a 14 month pilot experiment and six dogs for a later four month experiment. In the serum level of cholesterol or phospholipids, in the degree of fatty infiltration of the liver, and in the extent and severity of the arterial lesions, dogs receiving the largest amount of choline that they could tolerate did not differ from control dogs receiving no added choline.

Beriberi Heart in Iowa Veterans.—Five alcoholic veterans between the ages of 32 and 39 showed signs compatible with a diagnosis of beriberi heart disease, namely, cardiac failure, polyneuritis and cardiac enlargement. None of these Iowa residents had been a prisoner of the Japanese. In the occident, alcoholism and a thiamine-poor diet are jointly responsible for the majority of cases of beriberi. The thiamine intake of each of the five alcoholics had been approximately 0.15 to 0.26 mg. per 1,000 calories, while an average young adult requires 0.25 to 0.35 mg. of thiamine per 1,000 calories of balanced diet. Four patients showed moderate improvement of signs of congestive failure with rest and the usual hospital diet. Specific therapy consisted of administration of thiamine in daily doses of 20 mg. intramuscularly and 20 mg. orally. In addition, a high protein diet was given with oral and parenteral supplements of all vitamins. All patients improved after treatment, and, in two instances, there was significant reduction in cardiac size. Edema and symptoms of congestive failure disappeared in seven to 10 days, but two patients had persistent tachycardia for several weeks. The loss of edema may have been accelerated in four instances by sodium restriction. Maximal decrease in heart size occurred in from one to two months. Although none of the author's patients had a control period of thiamine-free diet, their response to therapy was typical of beriberi heart disease. Because beriberi is a reversible form of heart disease, as shown by these five patients, its early diagnosis is important.

School Health Program for Children with Heart Disease.—The high death rate from rheumatic heart disease among school children in Colorado and in Denver stimulated special interest in this disease. A rheumatic fever diagnostic service was developed. The Colorado Heart Association directs the policies of the clinic and has assumed an increasing share of the expense. Work of the clinic greatly sharpened the awareness of both the physicians and the general public to the problems of heart disease in children. During the first four years of its operation, 3,235 children were referred to the Denver Rheumatic Fever Diagnostic Service; 16.2% were shown to have rheumatic heart disease, and 6.2% were proved to have congenital heart defects. A small group were considered to have potential rheumatic heart disease and are being watched. Children classified as having possible, potential, or proved rheumatic heart disease are urged to have reexaminations the next year, or even sooner if evidences of the rheumatic state recur or other adverse conditions intervene. The prevention of false cardiac cripples is as important as adequate care in the real cardiac cases. In this selected group of children with heart murmurs or evidences of the rheumatic state, 67.3% had no cardiac disease. Children with active rheumatic fever are placed under medical treatment at once, either in private hospitals, at home, or in clinics. Children with congenital heart disease face a far brighter future than even a decade ago.

Interstitial Myocarditis in Children.—The occurrence of interstitial myocarditis in two children, one aged 11 months and the other six weeks, is reported. In both cases endocardium and epicardium appeared to be involved in the inflammatory process, although less extensively than the myocardium. Since this has been shown by others in similar cases, a revision of the belief that endocardium and epicardium are spared in this condition is indicated. Signs of an upper respiratory infection were the outstanding symptoms in the first case and signs of a gastrointestinal disorder in the second case. There was an interval of 26 hours in the first case and four days in the second case between the onset of the symptoms of illness and death, which occurred suddenly and unexpectedly. Interstitial pneumonia was a concomitant observation in both cases. The causative agent could not be demonstrated in either case. An analysis of the features of these and similar cases cited in the literature suggests that so-called isolated myocarditis in children is, in reality, a manifestation of a more generalized disease process and that a number of factors and agents irrelevant and apparently of a mild nature per se may lead under special circumstances or in predisposed persons to severe myocardial complications.

Endemic Amebiasis.—Frazier found 568 cases of endemic amebiasis among 3,000 patients at a school for the mentally deficient in Orient, Ohio, between 1946 and 1949. The disease is apparently endemic in humans, with increased incidence in areas of poor sanitation. Heretofore, there have been no factually based estimates on its incidence in this Ohio area. The incidence of endemic amebiasis in newly admitted patients was significant. The higher incidence within the institution was caused by patients of infantile and childish levels of hygienic behavior. The disease is most frequent in patients of lower mental levels. The frequency among idiots was three times that among morons, and among imbeciles it was twice that of morons. Sex difference was pronounced, with a ratio of 10 affected males to one affected female. Early in the study, the predominant symptoms were those of diarrhea or dysentery with varying degrees of physical deterioration. Later, pallor, weight loss, and abdominal pain became signs of greater frequency. These signs were not always associated with diarrhea or dysentery. Irritability, anorexia, headache, fatigability, or emotional depression may appear to dominate the picture. Although the signs and symptoms may be characteristic, they are not pathognomonic. Diagnosis rests on identification of the organism in the stools by microscopic examination. Acute and chronic appendicitis, hemorrhage, colitis, anemia, hepatitis, cholecystitis, malnutrition, and carcinoma present problems in differential diagnosis. The mere presence of the ameba does not explain the patient's symptoms, and further diagnostic work, including therapeutic tests, is required. All cases, symptomatic or not, should be treated, since extensive pathology may occur without obvious symptoms. Three classes of drugs were used in these cases: (1) the oxyquinolines, in the form of diiodohydroxyquinolone (diodoquin®), chiniofon, or iodochlorhydroxyquin (vioform®); (2) an arsenical in the form of carbarsone, and, within certain limitations, (3) the ipecac derivative emetine hydrochloride. Improvement was usually noted in two or three days, and symptoms were controlled in a week or two. Permanent elimination of the organism often required prolonged and varied treatment. There were four deaths in 76 cases in 1946; these were diagnosed late in the course of the disease, before adequate therapy could be used. There were four deaths in the years 1947-1949. Frazier further reports that the newly developed drugs chloroquine and the thioarsenites offer promise in the therapy of endemic amebiasis.

Moth Ball Poisoning.—A boy 2 years, 9 months old was admitted to the hospital because of anorexia and listlessness of four days' duration and frequent vomiting of two days' duration. This was followed by fever and flushing of the face. On the morning of admission he passed a quantity of port wine-colored urine, and his mother noticed pallor and a yellow tint of his skin. The tentative diagnosis was acute hemolytic anemia of Lederer. The mother stated that just prior to the onset of the child's illness she had found him playing with moth balls. The hemolytic process continued from three to seven days, during which time transfusions were necessary to replenish the rapidly hemolyzed erythrocytes. To prevent crystallization of hemoglobin in the kidney with subsequent anuria the authors kept the urine alkaline by giving 0.6 gm. of sodium bicarbonate every four hours. Since recovery was apparently complete with this therapy, a diagnosis of acute poisoning was suggested. Further observations will determine whether naphthalene poisoning is the most frequent cause of Lederer's anemia. If symptoms like the ones described here occur in a child of the "poisoning age," they should suggest naphthalene poisoning to the clinician.

*Treatment of Pulmonary Hydatid Cysts. V. Armand Ugón.—p. 369.
*Radiology After Pneumothorax. R. Racine.—p. 407.

Treatment of Hydatid Cyst of Lung.—From 1944 to 1950, Armand Ugón observed 190 cases of hydatid cyst of the lung. Treatment was surgical. In a first group of 129 patients the operation, performed by the transpleural route, consisted of enucleation of single unilocular hyalin cysts (78 cases) or removal of parasitic remains after recent rupture of the cyst (51 cases). In a second group of 55 patients with multiple hyalin cysts localized in one lobe of the lung, with vomica formation far in the past or with bronchiectatic hydatid cavities, the treatment consisted of lobectomy (41 cases), atypical pulmonary resection or cystectomy (10 cases), and pneumonectomy (four cases). In a third group of six patients puncture and drainage of the cyst were performed. In the whole group of 190 patients there were two deaths, one in the group of 10 patients who had atypical resection of the lung and one in the group of six patients who had puncture and drainage. The actual mortality rate of 2% in the whole group as compared with 20% in the last decade shows the improved prognosis for the patients, which results from advance of surgical treatment of the disease.

Radiology of Post-Pneumothorax.—Racine discusses the roentgen aspects of the lung after discontinuation of pneumothorax in 55 patients of both sexes above the age of 10. The type of pulmonary tuberculosis for which pneumothorax was established was cavitary in 36 cases and infiltrating in 19 cases. Collapse was good in 45 patients and partial in six. In four cases pneumothorax failed to collapse the diseased portion of the lung. The duration of collapse varied from less than six months to more than four years. Pneumothorax was discontinued because of clinical cure in 35 patients, pleurisy in eight, progressive pleuropulmonary adhesions in seven, contralateral pulmonary lesion in three, and abandonment of treatment by two patients. The author found that pneumothorax often produces irreversible parenchymatous or pleural lesions of the lung that are demonstrable roentgenologically. Pleural lesions include adhesions, pleurisy, and the complications of pneumolysis. Pleural lesions that are not seen by roentgen examination are visible by pleuroscopy. Pulmonary lesions are acute and diffuse in cases of diffuse pleurisy and are located at the bases of the lung only when the lesion is the result of a pleural synechia limited to the basal zone. Retraction of certain zones of the lung causes structural and morphological changes of the bronchi that are visible by bronchography. The author shows, by illustrations, the roentgen aspect of the reexpanded lung and the bronchographic changes caused by pneumothorax as he observed them in the aforementioned patients.

*Investigation on Problem of Soot Lung and on Injurious Effects of Pure Coal Dust in Dust of Coal Mines. H. Gärtner and F. W. Brauss.—p. 253.

Paralysis Caused by Injections.—According to one estimate, injuries in connection with injections have an incidence of about one in 100,000, including abscesses, phlegmons, gas gangrene infections, and injuries to nerves. Toxicity of the injected drug or a wrong technique are responsible for the nerve injuries resulting in paralysis. Subcutaneous or intramuscular injections should never be made into the upper arm, because injury to the radial nerve is possible. Intravenous injections made into a vein in the bend of the elbow should not employ the basilic vein, because in cases of accidental paravenous injection the median and ulnar nerves are easily injured. In cases of intragluteal injection it is not only important that the injection be made in the upper external quadrant, but the direction of injection is also important, and it should never be made more than 4 or 5 cm. deep. When a nerve is injured during injection the patient may complain of a painful sensation as is experienced during electrization. Paralysis may be evident at once or may develop later. The prospects of complete recovery from paralysis are slight when the injection was made into the nerve. When the injection was made close to the nerve, large quantities of isotonic sodium chloride solution should be injected. In the milder cases of paralysis massage, electric treatment, and exercises might produce improvement. In serious injuries in which there is no sign of regeneration the nerve should be exposed, but only rarely will this be adequate to release the nerve from the constricting cicatricial tissues. If nervous conduction is completely interrupted, resection and subsequent nerve suture may be tried.

Soot Lung and Effects of Coal Dust.—Roentgenologic examinations were made on the lungs of the employees of a plant producing lampblack (soot). Two types of soot were produced in the plant in question: so-called flame soot and gas soot. Exposure to the inhalation of soot was especially great in the workers who removed the soot from the flame-soot chambers and also in the workers who produce the gas-soot and in those who pack the soot. Of 189 workers who were thoroughly investigated 13 had fully developed and 18 incipient pulmonary changes; that is, more than 16% had such changes. After commenting on the importance of the length of exposure and the appearance of the roentgenologic shadows, the authors say that the inhalation of soot may continue without harmful effects. In some of the workers, roentgenologic changes appear in the lungs after many years of exposure, but functional impairment is minimal and the workers are able to continue in their occupation, so that the term dust-lung disease is really not justified. The harmfulness of pure carbon in the form of soot, graphite, or coal dust is evaluated from reports cited in the literature. Pneumoconiosis in coal miners differs according to region; for example, the coal miners in the Ruhr region, who are exposed more to rock dusts than the miners in South Wales, have a silicosis modified by coal dust, whereas, in the mines of South Wales, the coal dust factor plays a more important part.

*Lobectomy, Segmental Resection, and Pneumonectomy for Pulmonary Tuberculosis: Observations on 200 Cases. L. D. Eerland.—p. 275.
Serologic Reactions in Diagnosis of Rheumatic Diseases. S. A. den Oudsten and P. E. van Loghem-Langereis.—p. 289.

Pulmonary Resection in Tuberculosis.—Eerland describes his experiences in the course of 200 pulmonary resections that he has performed on tuberculous patients since May 1943. This number included 111 pneumonectomies, 73 lobectomies, and 16 segmental resections. There were 110 men and 90 women. Resection may prove difficult in extremely obese patients, in patients who have been sick for years, and in those who also have extrapulmonary tuberculosis. This last factor is not a definite contraindication but makes caution essential. Resection may be technically difficult in patients who have undergone other collapse operations, particularly extrapleural pneumothorax or thoracoplasty. While the patient is being prepared for pulmonary resection, breathing exercises should be employed, and the patient should learn to control the thoracic as well as the abdominal respiration. Administration of the B complex vitamins and vitamin C is also advisable. Streptomycin is given from seven to 10 days before and may be continued for three or four weeks after the operation. Paraaminosalicylic acid is also of great value; it may be continued for from six to eight weeks after the operation. The postoperative mortality rate was 4.5%. The death of nine patients was connected with the operation; four died later. The sputum had become negative in 172

An asterisk (*) before a title indicates that the article is abstracted. Single case reports and trials of new drugs are usually omitted.

of the 187 patients who were still alive on Oct. 1, 1950. Of the 187 patients, the prognosis was definitely unfavorable in four, and 70 were still in the sanatorium. Of the 117 who had been discharged, 104 had resumed their occupations.

Primary Ovarian Cancer as Complication in Pregnancy and Delivery. R. Feniger.—p. 61.

What Is Mental Hygiene?—Smitt outlines some of the main features of the concept of mental health. The aim of the mental health movement, he says, is to help the individual to live harmoniously with his fellow men. The cultural patterns in large parts of the world will have to be modified. More considerate upbringing of children and kinder treatment of adults would probably decrease some biosocial problems, such as maladjustment of children, psychosomatic diseases, psychoses, neuroses, alcoholism and criminality. The medical profession, to be adequate and up-to-date, must enter into biopsychosocial preventive work. The evolution of medicine in the direction of prevention is indicated by the establishment of the World Health Organization and the World Federation for Mental Health.

Why and How Early During Childhood Should Squinters be Operated on? G. de Ocampo.—p. 118.

Prefrontal Lobotomy for Relief of Pain.—Javier and Lucas feel that when pain is accompanied by fear or anxiety or when it is followed by panicky conduct due to remembrance of previous racking experiences, then the patient is a good subject for lobotomy. Previous experiences with lobotomy suggest that the more posterior lobotomies are most effective in psychotic patients, whereas more anterior ablations are more advantageous for the treatment of intractable pain, because the resultant personality changes are less. The authors describe a modification in which the cut is made closer to the extreme frontal pole of the cortex. Their procedure is intermediate between the closed method of Freeman and Watts and the open technique of Lyerly, Poppen, Penfield, and others. The treatment was used in four patients with intractable pain from metastatic carcinoma, and it relieved pain and mental suffering without causing personality changes. The authors regard it as the operation of choice for relief of intractable pain and the associated mental suffering.

•Central and Peripheral Hematological Picture in Normal and Pathological Subjects Treated with High Doses of Synthetic Chloramphenicol. G. Binaghi, U. Carcassi and C. Pirastu.—p. 563.
Calcified Splenic Hydatid Cyst. F. Santa Cruz.—p. 578.

Effect of Chloramphenicol on Hematological Picture.—The authors direct attention to the conflicting opinions in the literature on the toxicity or lack of toxicity of synthetic chloramphenicol on the blood and the blood-forming tissues. They studied the behavior of the myelogram, and they performed studies of the peripheral blood of two patients with brucellosis and two normal persons 24 hours before administration of chloramphenicol and 24 hours after completion of treatment. The drug was given orally, the racemic form to patients and the levorotatory form to normal persons, in a total dose varying between 45 and 53 gm. of the racemic drug, in nine and 12 consecutive days respectively, and in a total dose of 25 gm. of the levorotatory form in five consecutive days. The results showed that chloramphenicol, in either the racemic or the levorotatory form, has no toxic action on the blood and blood-forming tissues, contrary to previous reports in the literature of a few cases, which were probably due to infection in patients with constitutional lability of the blood.

•Postcricoid Pharyngo-Oesophageal Perforation Due to Endoscopy. L. Knox—p. 37.
Bilharziasis in the Transvaal: Its Diagnosis and Incidence. R. L. van Wezel.—p. 44.

Pharyngoesophageal Perforation in Endoscopy.—While perforation of the esophagus after endoscopy has long been recognized as a danger, particularly where there is a lesion such as a carcinoma or a stricture, it is only in recent years that attention has been drawn to perforation occurring in a healthy esophagus in the postcricoid area, i. e., at the pharyngoesophageal junction. A total of 17 postcricoid perforations following gastroscopy have been recorded. In the past most of these patients were treated expectantly. Of the 17 patients, 10 died. Goligher was the first to recommend urgent exploration of the pharyngoesophageal area, with immediate suturing of any tear, as soon as surgical emphysema is noted in the neck after endoscopy. A patient in whom Goligher did this made a satisfactory recovery. Knox here reports a case that leads him to give emphatic support to Goligher. Delay in operation led to an increase in the friability of the esophageal wall, with a consequent cutting through of the stitches. Failure to operate when surgical emphysema was noted was an error, since the degree and the rapid development of the emphysema should have indicated that the laceration was not small and therefore not likely to seal spontaneously. A delay of five months in the hope that natural closure of the fistula would occur achieved nothing but discomfort for the patient.

•Comparative Investigations on Galli Mainini and Friedman Pregnancy Reactions. J. V. Thorborg.—p. 199.
•Clinical Experiences with Mainini Test. Bufo Pregnancy Reaction. C. F. Felding.—p. 203.
Leukemia in Children in Denmark 1942-1949. P. E. Andersen.—p. 205.

Comparative Investigations on Galli Mainini and Friedman Pregnancy Reactions.—Comparing Galli Mainini's pregnancy reaction in the common toad (the bufo reaction) with Friedman's pregnancy reaction in 1,042 cases, Thorborg found that the bufo reaction was slightly less sensitive than the Friedman test, but that all positive bufo reactions were correct. A positive bufo reaction is considered as certain as a positive Friedman reaction, or possibly more certain, but a negative Friedman reaction must be regarded as more certain than a negative bufo reaction. The Friedman reaction is to be preferred in cases in which a moderate gonadotropin excretion may be expected, i. e., at a very early stage of pregnancy, in the last half of pregnancy, and in extrauterine pregnancy. The advantages of the bufo test are its speed (about 24 hours as against 40 or 48 hours for the Friedman test), its inexpensiveness and simplicity, and the small space required for storing the toads.

Clinical Experiences with Mainini and Bufo Pregnancy Tests.—Felding says that with due regard to its field of application, which on the basis of two years' experience he sets at about six weeks after the last normal menstruation for the lowest limit and four months' pregnancy for the upper limit, the bufo reaction proved reliable in 250 positive reactions. A positive reaction has always proved to be correct. The bufo test is less sensitive than the Friedman reaction and should be supplemented by it if the result is negative and there is reason to suspect extrauterine pregnancy, very early pregnancy, or far advanced pregnancy. Its advantage over other more sensitive tests is that the reaction to it more quickly becomes negative in incomplete abortion and probably also in missed abortion. It is readily performed and inexpensive.

BOOK REVIEWS

The Neurosurgical Treatment of Traumatic Paraplegia. By J. Lawrence Pool, M.D., Professor of Neurological Surgery, College of Physicians and Surgeons, Columbia University, New York. Publication number 83, American Lecture Series, monograph in American Lectures in Surgery, edited by Michael E. DeBakey, M.D., Professor of Surgery, Chairman, Department of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Kentucky. Division of Neurosurgery, editor: Barnes Woodhall, M.D. Cloth. $3. Pp. 107, with 24 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1951.

Before World War II, patients who suffered a complete transection of the spinal cord rarely survived for more than a few weeks. Few patients who had suffered this type of injury recovered sufficiently to become even partially rehabilitated. Deaths resulted from infected decubitus ulcers, infections of the urinary tract, or respiratory complications. Only two or three hospitals had the trained personnel, the equipment, and the financial resources necessary for the tedious task of rehabilitating patients who were paralyzed because of spinal cord injuries. The paraplegic was indeed the "forgotten man."

During and since World War II, lessons learned and taught by Deaver, Rusk, Munro, Pool, and their colleagues have been used to develop other paraplegic rehabilitation centers. Several of the best of these are to be found in Veteran's Administration hospitals.

In this excellent monograph, Dr. Pool has briefly reviewed the history of paraplegia, its etiology and pathology, and in a very clear and concise manner has discussed diagnosis and treatment. Treatment, as outlined by Dr. Pool, begins with the place *and time of injury to the patient and is carried through a recommended* program of rehabilitation. All who treat traumatic paraplegia should have a copy of this splendid little book.

Personnel Administration in Public Health Nursing. By William Brody, Director of Personnel, New York City Department of Health. Cloth. $3.25. Pp. 209, with 12 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1951.

With expanded public health programs either contemplated or already under way, an increase in public health nursing personnel can be expected. More emphasis will necessarily be directed toward sound principles of personnel management in dealing with this particular group. This volume stresses that personnel administration as an applied science can contribute as much to health administration as it has to other public and private, social and industrial services. Specific attention is directed toward those aspects of employment that are unique to a social and educational field like public health nursing. The author emphasizes that the person must be allowed the fullest possible personal and professional growth with stimulation and adequate appreciation of creativeness, special skills, and knowledge. Furthermore, individual personal differences in emotions, attitudes, and habits must be taken into account.

Such subjects are discussed as types of service and methods of recruitment, selection, and service evaluation. The importance of inservice training and working conditions, which involve salary, leaves of absence, promotion, resignation, retirement, and dismissal, are considered briefly.

This volume should serve to stimulate progressive thought and action in personnel administration in public health nursing. While it affords only a brief discussion of the many complex aspects of the field, it tends to emphasize those points which are most obviously vital to efficient administration. The volume is directed toward public health nursing practitioners and students and to all those associated with public health nursing in an administrative capacity. It should be of academic and practical interest to these groups.

Heart Disease: Its Diagnosis and Treatment. By Emanuel Goldberger, B.S., M.D., Associate Attending Physician, Montefiore Hospital, New York. Cloth. $10. Pp. 651, with 90 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1951.

When a new book on heart disease is published, one may well ask why there is need for any more books on the subject in view of the plentiful supply of such treatises. It was with this point of view that this book was analyzed. In its favor is the fact that it is complete in its scope; its bibliography is up-to-date, and some of the illustrations and tables are very informative, particularly those on fluoroscopy and electrocardiography. Furthermore, this book attempts to integrate into a pleasing whole the old traditional viewpoint of cardiovascular disease with the more modern methodologies which have sprung up recently, and in this effort, excellent coordination is achieved. The format is pleasing, although it might have been better not to have so many subheadings, and it might have been advisable to avoid having so many cross references (with page number) within the text. The text is also uneven, at times being somewhat like a compend and at other times being rather lengthy and involved. It is, therefore, an uneven presentation, and sometimes one has the feeling that there is not that maturity of judgment that is expected in a textbook on an important subject such as heart disease. Of course, there are many isolated items in the text with which one cannot agree; some of these are matters of personal judgment, but some of them are serious content errors. One gets the feeling that the author has read the literature extensively and has summarized a great deal of this in some areas without the benefit of a large amount of personal experience.

The author starts out in the first section with the normal heart, methods of physical examination, and the special methods of laboratory examination. In the second section he presents the abnormal heart, its symptoms and signs, and the roentgenographic, electrocardiographic, and other circulatory examinations. In the third section, he deals with cardiac syndromes like congestive heart failure, shock, syncope, the anginal syndrome, neurocirculatory asthenia, and the cardiac arrhythmias. In the fourth section, there is a systematic description of the cardiac abnormalities, with congenital heart disease as the starting point. This is followed by myocarditis, rheumatic fever, rheumatic heart disease, bacterial endocarditis, syphilitic and hypertensive heart disease, coronary heart disease, cor pulmonale, diseases of the pericardium and of the blood vessels, the heart in endocrine disorders, tumors of the heart, and trauma. In the last section, he deals with such things as pregnancy, surgery, and employment. The scope of the book is ambitious, and if the author has not always come up to expectations, this should not deter from the fact that the reader will find this book of value as a reference source of the present state of knowledge.

Organized Health Services in a Rural County. By Milton I. Roemer and Ethel A. Wilson. [This study was conducted as a cooperative research project between Monogalia County (West Virginia) Health Department and U. S. Public Health Service, States Relations Division.] Paper. Pp. *144. Washington, D. C., 1951.*

This is a mimeographed brochure of considerable length and detail, dealing with the study of organized health services in Monongalia County, West Virginia. This study was conducted as a cooperative research project between the county health department and the United States Public Health Service, with participation of West Virginia University departments of medicine, sociology, and social work. It should be of interest as a pattern for those interested in making similar studies or participating therein. There is nothing in the brochure or in the accompanying information to indicate whether it is available outside the state and, if so, the price. Presumably the county health department or the States Relations Division of the Public Health Service would answer inquiries from interested persons.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

History of Pharmacy: A Guide and a Survey. By Edward Kremers, Ph.G., Ph.M., Ph.D., Sc.D., and George Urdang, Ph.G., D.Sc., Nat., Sc.D., Professor of History of Pharmacy, University of Wisconsin, Madison. Second edition. Cloth. $7.50. Pp. 622, with illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1951.

This book is a completely revised and enlarged edition. It retains the approach characteristic of the original edition, which presents facts and events as part of an integrated picture of the development of pharmacy rather than the chronologic narration of historical details. While emphasis is placed on the history of American pharmacy and the contribution of its disciples, a significant portion of the book is devoted to the development of pharmacy on the Continent and international pharmaceutical trends.

The volume is divided into four parts. The first part is devoted to the background of pharmacy in earlier civilization and its transition from ancient times through the Middle Ages. The birth of professional pharmacy in Europe and its development in the leading countries on the Continent comprise the second major portion of the book. Part three records the history of pharmacy in the United States. It is divided into two sections: the development of pharmaceutical practice from colonial times through the period of westward expansion, and an outline of the growth of associations, the rise of legislative regulation, the development of education, the literature, and the economic structure of American pharmacy. Part four highlights the discoveries, inventions, and other contributions to society by pharmacists. A bibliography, chronology, glossary, and an index of one hundred fourteen pages complete the remaining portion of this volume.

The full significance and value of this book is perhaps best stated in the concluding sentence of the text: "If we do not wish to lose the great men of and deeds that emerge from pharmacy, we must cultivate the ground from which they spring." The authors of the "History of Pharmacy" should take pride in the knowledge that they have not only enriched the literature of pharmacy but have provided a book which should be a source of inspiration to all who have espoused this old and honored profession.

Blood Groups in Man. By R. R. Race, Ph.D., M. R. C. S., Director, Medical Research Council Blood Group Research Unit, Lister Institute, London, and Ruth Sanger, Ph. D., B.Sc. With foreword by Professor R. A. Fisher, F.R.S. Cloth. $6.50. Pp. 290. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This book contains an up-to-date, authoritative discussion of blood groups and their inheritance. In addition to ABO groups, the newer blood groups such as MN, P, Rh, Lutheran, Kell, Lewis, and Duffy are reviewed, and methods for identification of blood group antibodies are described. The significance of blood groups in hemolytic diseases and blood transfusions, and the contributions of blood group investigations to problems of parentage and identity are reported. The discussion is supplemented with numerous tables and charts. Each chapter concludes with a list of references, and both an authors' index and a subject index are included at the end of the book. This volume should be a useful reference for physicians, geneticists, anthropologists, members of the legal profession, and all others interested in blood group research and its practical application.

Somatic and Psychiatric Treatment of Asthma. Edited by Harold A. Abramson, M.D., Associate Physician and Chief, Allergy Clinic, Mount Sinai Hospital, New York. Cloth. $11. Pp. 751, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1951.

This is a rather exhaustive treatise on the treatment of asthma, with special consideration given to psychiatric management. The book consists of six parts. Part one deals with basic concepts, and here the chapters on the physiology and psychodynamics of respiration and air flow in asthma are especially valuable. Part two concerns general methods of testing and treatment. Peshkin's chapter on "Critical Evaluation of Diagnostic Tests for Sensitization" is a complete and noteworthy contribution. Part three includes a discussion of inhalant allergens and their use in specific therapy. Part four deals with somatic therapy. This chapter contains contributions by many authors, and there is much overlapping and repetition of discussions. One may well question the wisdom of having separate chapters on intravenous treatment, antihistamines, inhalation of gases, aerosol therapy, and experimental production of asthma with aerosols in man. Part five is a discussion of psychotherapy. On the whole, the psychosomatic approach in this phase of therapy is dealt with in a common sense manner, although one may find it difficult to accept the emphasis given to the concept of maternal rejection. Part six deals briefly with some aspects of asthma therapy in Latin America. This part seems superfluous: the necessary botanical material could have been included in a paragraph or two in another portion of the book.

This book has all the faults that can occur in a compilation by a large group of authors. Overlapping discussions and multiple haphazard division of subjects naturally result in "padding." Quality is distinctly uneven. There are scholarly chapters representing material never found before in complete form in a textbook. On the other hand, there are also chapters so dogmatic and elementary that they seem not to fit in with other portions of the book. This volume will be valuable to the allergist and physiologist, and it will serve internists because of the special features that it contains. However, it is not the type of textbook that can be recommended particularly for the embryo allergist, the medical student, or the average practitioner who is as yet inexperienced in allergy.

The Doctor: His Career, His Business, His Human Relations. By Stanley R. Truman, M.D. Cloth. $3. Pp. 151, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1951.

The medical student, the recent graduate, and the mature physician will each find much of interest and value in this book. It is written from the standpoint of a general practitioner of broad experience and of a thoughtful student of many of the problems that impinge on medicine today. It offers excellent advice and guidance to the young physician about to enter practice on such practical matters as location, selection, and equipment of an office and the various procedures necessary to establish oneself in a community. It goes further and instructs him on how to adjust himself to his colleagues, to organized medicine, to his patients, and to society as a whole.

The discussion of many of the problems of medicine are brief and often didactic, since they merely express the author's views on a number of highly debatable subjects. Certain of these problems are oversimplified, but their presentation should serve to stimulate the physician to further inquiry and to arouse in him a feeling of responsibility for aiding in their solution.

Of especial value are the last three chapters dealing with the relation of the physician to his colleagues, to the public, and to his patients. The thread of idealism that runs through these chapters is properly balanced by a sense of reality. They are worthy of the thoughtful consideration of every physician interested in the enduring progress of medicine.

Paracelsus: Magic Into Science. By Henry M. Pachter. Cloth. $4. Pp. 360, with 12 illustrations. Henry Schuman, Inc., 20 E. 70th St., New York 21, 1951.

This book portrays in easily readable fashion the true history of the life, adventures, beliefs, and prophecies of a man who can be considered the founder not only of biochemistry and chemotherapy, but of experimental science itself. At the time of Paracelsus, chemistry was a technique rather than a science, but largely because of his efforts this craft won recognition among the sciences. In fact, he was the first to use the word "chemist," and the first to classify chemical substances.

In his search for truth and knowledge, Paracelsus traveled far and wide in a troubled world, disagreeing with the medieval folk-medicines and cures and refusing to believe patients doomed merely because the books did not prescribe a treatment. From his many travels, he brought home experiences that became the foundation of his doctrines in medicine and chemistry.

The fact that Paracelsus lived in the age of the Renaissance and the Reformation might explain his development of a philosophy that was to become the instrument of a radical departure from the conservative view.

Dr. Pachter's well-illustrated novel contains a wealth of historical facts interwoven with the biography of Paracelsus, making it extremely worth-while reading.

QUERIES AND MINOR NOTES

ATHEROSCLEROSIS AND ARTERIOSCLEROSIS

To the Editor:—*Please explain the difference between atherosclerosis and arteriosclerosis.* *M.D., Florida.*

Answer.—Atherosclerosis, so named in 1906, is the most important chronic arterial disease. It is responsible for at least 90 per cent of coronary artery disease, for example. It is almost exclusively a disease of man among mammals. It occurs in birds, notably in chickens fed for market. In these animals it is dominant in the male, as is true in man. It is a specific focal disease which arises in selective sites in the arterial system, where scavenger cells, macrophages carrying excess crystalline esters of cholesterol, invade the arterial intima in waves. The esters of cholesterol are irritant and slowly stimulate the growth of connective tissue. Intermittent waves of invading cholesterophages in time produce fibrous thickening of the intima and narrowing of the arterial lumen. These conditions in the coronary arteries favor thrombosis or insufficiency of the vessels. Calcification is a terminal deposit in necrotic lesions. Reproduction of human lesions follows feeding of cholesterol in rabbits or chickens and feeding of cholesterol and thiouracil in dogs.

Arteriosclerosis is the older term (1830) applied to the common chronic arterial disease, especially of the aorta, when we knew little about arterial disease. As used today it is all-inclusive, embracing atherosclerosis, Monckeberg's sclerosis and diffuse arterial changes, such as dilatation, tortuosity, thinning or thickening, which are probably due to wear and tear and age, particularly in an already diseased vessel. Monckeberg's sclerosis is a primary necrosis of the media in peripheral arteries, in rings or continuously, with fixation of the vessel, by calcification or ossification, in the dilated position. Narrowing of the lumen, when it occurs, is due to engrafted atherosclerosis.

MULTIPLE SCLEROSIS

To the Editor:—*A 34 year old married woman had her first attack of multiple sclerosis in March 1949, with peripheral sensory derangement involving one arm, mild ataxia and exaggeration of most reflexes lasting about four weeks. A remission of subjective symptoms lasted one year; then she had a severer attack, with general cutaneous hyperesthesia, ataxia, nystagmus with diplopia, severe headache and bladder retention lasting six to eight weeks. She has had a less complete remission since this last attack and has been able to attend to most of her household duties. Many of the objective neurological findings have persisted. Bladder function is normal. Can a similar exacerbation be predicted? Is there any new therapy?* *L. M. Lide, M.D., Florence, S. C.*

Answer.—It is characteristic of multiple sclerosis that the possibility of exacerbations cannot be predicted in any specific way. Some workers believe that alterations in capillary fragility occur before an exacerbation is clinically detectable. This does not, however, have universal acceptance.

No statistically valid seasonal variations are known to exist. However, this statement must be qualified with the observation that unusual climatologic stress may precipitate reactivity of the disease in the way that other stresses, such as pregnancy, infection and emotional disturbances, have been observed to antedate exacerbations.

There is no new therapeutic regimen for multiple sclerosis. It is considered that supportive measures, such as adequate nutrition with vitamin supplements, appropriate patterns of rest and exercise and dynamic psychotherapy, all play an important role in enabling the patient to withstand the rigors of the disease.

THROMBOPHLEBITIS

To the Editor:—*A patient had thrombophlebitis of the homolateral extremity following herniorraphy. This became chronic with recurrent acute exacerbations. Seven years later thrombophlebitis of the opposite lower extremity developed. Six years later repeated pulmonary infarctions occurred, despite anticoagulation therapy and bilateral femoral ligations. Eventually the patient submitted to ligation of the inferior vena cava. At operation involvement of both iliac veins was observed. In such a situation, is it possible that the iliac veins and veins of the second extremity were involved in that order from the original source?*

Elmer A. Kleefield, M.D., Forest Hills, N. Y.

Answer.—The history as outlined is typical of a progressive thromboembolic disease that originated with postoperative thrombosis. The original level of this thrombosis may have been in the foot or calf muscles of the affected extremity or in the pelvis. The prolonged progressive course may be due to several factors. The patient himself may have had a tendency to clot; this thrombophilia seems to be familial. Once a thrombosis develops, the circulatory stasis that it produces is an additional factor in the production of ascending or descending thrombosis. The clot itself has a propagating quality. Other factors that help to reactivate a latent thromboembolic disease are trauma to the affected extremity, inadequate elastic support and continued smoking.

Therapeutic measures have a great deal to do with persistence of thromboembolic disease. Insufficient anticoagulant therapy, either with heparin or bishydroxycoumarin prolongs the disease and may increase the clotting tendency. Anticoagulant therapy in acute thrombosis must be intensive. Token doses are worse than no therapy at all. When vein ligations are done, they must be above the level of the thrombus; superficial femoral ligations are useful only when the clot is still below the knee. When they are done in the presence of iliac thromboses or phlebitis of periprostatic, perirectal or perivesical origin, they may even stir up a latent periphlebitic process.

Vena cava ligation was the method of choice in this case, since all other methods failed. Even so, patches of periphlebitis may occur on both lower extremities unless the patient's thromboembolic disease has been eradicated.

SEVERE DRYNESS OF MOUTH

To the Editor:—*A 59 year old woman complains of dryness of the mouth and pharynx of 17 months' duration. This is so pronounced that she finds it difficult to swallow food. She had infected teeth, blood pressure of 260/140 and urine with specific gravity of 1010, with fluid restriction. The tongue and mucous membranes were so dry that the tongue depressor stuck to them as if glued. Otherwise the results of physical examination were normal. After extraction of the teeth she felt better, but her mouth did not change. Her blood pressure dropped to 140/110, and the specific gravity of the urine would occasionally be as high as 1016. Her nonprotein nitrogen is 32 and sedimentation rate 25 mm. Have you any suggestions?*

Charles A. Rose, M.D., Hornell, N. Y.

Answer.—The Jacksons (Diseases of the Nose, Throat, and Ear, Philadelphia and London, W. B. Saunders Company, 1945, p. 145) in discussing Mikulicz's disease mention dryness of the mouth and the conjunctiva which may be due to the replacement of secretory tissue by an infiltration of lymphatic cells. In xerostomia, others mention the role of dehydration following diarrheas (typhoid, cholera) and severe febrile diseases. Chronic kidney disease and epidemic parotitis are implicated, as is the use of belladonna and its derivatives and opium. Dryness following roentgen treatment of facial structures is well known. Diabetes mellitus and insipidus are included

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

as causes of xerostomia. One author mentions its occurrence in elderly women, in whom it is said to follow mental shock. The sense of taste is said to be lost, and speaking and swallowing are difficult. Because of dehydration, the tongue resembles crocodile skin (The Merck Manual, ed. 8, Rahway, N.J., Merck & Co., Inc., 1950, pp. 309-310).

Some of the loosely described symptoms given above may really belong to what is more recently described as Sjögren's syndrome, a complex characterized by dryness of the conjunctiva, mouth, nose, pharynx, trachea and bronchi. Gastric and vaginal secretion may be minimal. Depending on the location, and possibly owing to the action of some secretoinhibitor mechanism, there are symptoms divisible into ophthalmic, oropharyngeal and a so-called classic type, in which the chief complaints are swelling of the salivary glands, fever, and gastrointestinal complaints.

Cooperman (Cooperman, H. O.: *Ann. West. Med. & Surg.* 4:344, 1950) suggests that the cause may be too little acetylcholine or too much cholinesterase at the end organ. He suggests the use of diethylstilbestrol and methyltestosterone, because of the possible relation of the complaints to the menopause, and pilocarpine, because of its cholinergic character. Glycerin mouth washes are said to be helpful; nasal obstruction should be treated to minimize mouth breathing and lost teeth replaced by well fitting dentures to help avoid respirational dryness.

HOT FLASHES IN A MAN

To the Editor:—*For the past year I get "hot flashes" affecting the upper part of the body and face, lasting a few minutes and concluding with perspiration of the back and the axillas. These "flashes" usually occur several times a day with free intervals of several weeks or months; they occur at any time of the day but, as a rule, in a hot room, and there is a general intolerance to heat. Otherwise I feel well but tired. My blood pressure is 150/105 mm. Hg. Eighteen months ago I had homologous serum hepatitis, and the cephalin flocculation test was still 2 + a few months ago. I have taken vitamin B complex in the usual dosage on and off for the last 18 months. The hepatitis was due to a blood transfusion I had received three months previously. Could the flashes be due to disturbed heat metabolism of the liver or to the vitamin B? Could the flashes be due to the "male climacterium?" I am 52 years old. Is there any treatment for this condition?*

M.D., New Jersey.

Answer.—The hot flashes which you describe probably do not bear any relation to liver function or to the administration of vitamin B. The possibility of the male climacteric should be considered, although this condition usually does not develop until after the age of 52. A therapeutic trial of androgen might be made, with intramuscular testosterone propionate injections, 50.0 mg. three times a week. If the hot flashes are caused by the male climacteric, they will disappear with this form of treatment.

TINGLING OF SOLES OF FEET

To the Editor:—*A man, 60, smokes two packages of cigarets a day. His dorsalis pedis artery pulsation is very good but he complains of burning and tingling of the bottoms of both feet which wakes him up at night. He obtains relief only by soaking his feet in cold water. His blood pressure is normal, and he has no cardiac symptoms or dropsy; the color of his feet is good. What can be done to relieve this patient?*

Aurbey L. Lewis, M.D., San Angelo, Texas.

Answer.—This patient's symptoms are suggestive of erythromelalgia, since the heat, burning, and tingling are relieved by cold water. Such a lesion may be on a vascular, a neurologic, or a purely functional basis.

Nothing has been said about the presence or absence of the posterior tibial pulse; this should be palpated and its pulsation or absence of pulsation noted. If the patient has no reflexes, particularly no achilles tendon reflexes, a complete neurological examination, including a spinal puncture, is important. It would be also necessary to exclude polycythemia, this being a frequent cause of erythromelalgia. X-rays should be taken of both feet, possibly on one film, and the presence or absence of osteoporosis noted. Cord lesions and even arteriosclerotic ischemia of the cord might produce the symptoms described.

Generally speaking, this man should have a complete examination and his neurovascular status evaluated; if nothing is found, large doses of thiamine hydrochloride and vitamin B_{12} might be administered for symptomatic relief.

BEAUTY SHOP OPERATORS

To the Editor:—*A beauty shop operator has been complaining for months of "tingling and bursting" in her fingers; at times they become numb. She is 55, shows pronounced nervousness and is otherwise normal. She has been taking small doses of thyroid extract for some time, because of a mildly abnormal basal metabolic rate. Hot water, massage, and moving the digits relieves the symptoms somewhat. Placing them in cold water does not precipitate the spell. There is no obvious discoloration. The patient seems to think that some cold wave permanent preparations may be responsible, especially since her right hand is affected primarily. I would appreciate your opinion.*

I. Alan Ulert, M.D., Houston, Texas.

This inquiry was referred to two authorities, whose respective replies follow.—Ed.

Answer.—Numbness and tingling of fingers in a 55 year old nervous woman is not uncommon. It is doubtful that such symptoms could have been connected with the use of ammonium thioglycolate. Detailed studies of the circulation, including a finger plethysmogram and capillary microscopic study, together with a study of sensory and vibratory sense could rule out a purely functional disturbance. "Bursting" pain is often aggravated by heat and relieved by cold, it is one of the symptoms of erythromelalgia and may be present without color changes.

Answer.—A review of the literature on cold wave preparations does not indicate that they have been proved responsible for "tingling and bursting" in the fingers. The only unfavorable reactions that have definitely been established as caused by cold waving preparations are sensitizations and irritations, and these occur very infrequently.

Beauty shop operators are more likely to suffer reactions than the occasional user of a home permanent. It is urged by all investigators that beauty shop operators wear gloves in handling these solutions, inasmuch as a severe incapacitating dermatitis can result if sensitization does develop.

Following is a summarizing statement of a report of the Committee on Cosmetics by Dr. A. J. Lehman (*J. A. M. A.*, **141**:844 [Nov. 19] 1949).

> The number of cold waves given each year employing salts of thioglycolic acid can no doubt be estimated in the millions. The number of complaints in comparison with the total number of applications is small. From rigorous laboratory evaluation of the hazards involved, it may be stated that the judicious use of ammonium thioglycolate as a hair-waving preparation should prove a relatively innocuous procedure. The majority of complaints from patrons and operators are probably due to the misuse of the product because of failure to heed directions or precautions. Allergic responses to the thioglycolates appear to have occurred only rarely. Allowance must also be made for allergic responses to the other ingredients, such as wetting agents and perfumes.
>
> It is believed that protection for the hands is essential in the case of operators or persons who have occasion to be exposed daily to varying amounts of the waving solution.

SPIDER NEVI

To the Editor:—*What can be done for the spiderweb-like veins, telangiectasis, I believe they are called, on the thighs of a healthy girl of 20?*

M.D., Florida.

Answer.—Spider nevi are small pinpoint-sized to pinhead-sized red spots with fine, weblike projections, which radiate from the center and are often associated with hepatic disease. They may show pulsation. Cutaneous spiderbursts, however, consist of a delicate network of fine venules, which have a central pool and frequently appear on the thighs of young women. Many more develop at a later date, especially during menopause. While an individual burst may be injected centrally with a drop or two of a sclerosing solution or touched with a fine electric cautery, the cosmetic effect is always doubtful and, of course, the appearance of new lesions is not prevented. Since the bursts are harmless and cause nothing but anxiety on cosmetic grounds, reassurance and covering powders or pastes are sufficient.

REHABILITATION OF THE APHASIC PATIENT

To the Editor:—*I would appreciate information regarding methods of rehabilitation of aphasias secondary to cerebral accidents. Some of these patients are unable to write because of residual involvement of the arms and hands.*

M. A. Gold, M.D., Butte, Mont.

Answer.—In evaluation of the aphasic patient for rehabilitation, the specific area of language disturbance (reading, writing, speaking) must first be determined. An aphasic is usually one of four types: (1) expressive, (2) receptive, (3) expressive-receptive, or (4) global (e. g., has complete losses in all language phases). The prognosis for retraining in language depends primarily on (1) age, (2) duration of aphasic symptoms, (3) motivation of the patient, and (4) his emotional status. The "expressive type" aphasic has the best prognosis for language therapy.

The methods employed in retraining all types of aphasics are similar to those used in language teaching for young children and in teaching the deaf. The materials used, although elementary, are adapted to adult interests. For the right hemiplegic, left-handed writing is taught concurrently with reading and speaking. The procedures in retraining an "expressive type" aphasic include: (1) utilizing all residual automatic speech, such as numbers, days, and other units which contain logical series; small successes are highly encouraging to the patient; (2) with the use of groups of pictures of objects (clothing, food), the patient is taught to write, read, and say the names of concrete, everyday objects; (3) teaching the patient to handle everyday language situations (e. g., writing letters, adding bills).

Joseph Wepman's "Recovery from Aphasia" (New York, Ronald Press, 1951) is recommended as an easy-to-read, comprehensive account of rehabilitation processes for the aphasic patient.

LEG PAINS IN CHILDREN

To the Editor:—*In the excellent discussion on "Leg Pains in Children," which appeared in Queries and Minor Notes, April 28, 1951, I should like to add that it is well to consider a functional origin. I recently examined two girls of different families, 3 and 6 years of age, in whom the complaint of leg pain at night appeared to be an attention-gaining mechanism. The physical examination in each instance, including postural appraisal, was quite negative. In both cases there was an unusual degree of reciprocal attachment between mother and child, as well as an interloper in the shape of a younger brother. One of the patients, the 3 year old, relapsed into bed-wetting after the arrival of the baby. The mother of each of these girls was in the habit of leaving her own bed at night in order to comfort the child. The patients have been treated solely along functional lines, one with great improvement, the other with apparent cure.*

I believe that a postural explanation for pain of this type should be consigned to the same attic where "growing pains" now rest in deserved oblivion. "Proper" posture is a dogmatic, not a normative, concept; hence postural flaws may be detected in almost any human, adult or child. We know by practical experience that "poor" posture can be decidedly symptomatic—at any rate the aching back and the sore knee become well after postural correction—but the symptoms are quite different from those mentioned above.

New Haven 11, Conn.

To the Editor:—*Whoever answered the question on "Leg Pains in Children" in* The Journal, *April 28, page 1393, was somewhat distracted when he read it. Possibly he was making out his income tax. I will try to give what I think is a better answer.*

Otherwise healthy and normal children who complain of severe pains in the legs do so, in most cases, because overfatigued muscles in the legs are cramping. Such fatigue and cramping may be due to simple hyperactivity, or it may be due to faulty foot mechanics and most frequently to congenitally short heel tendons. Pain in the pretibial area is most frequently caused by fatigue and spasm in the anterior tibial muscle brought on by the effort to overcome a congenitally contracted heel tendon. This may be aggravated by going barefoot and by low-heeled or heelless shoes, such as small children wear, and by tennis shoes, such as somewhat older children frequently wear. Raising the heels $\frac{3}{8}$ to $\frac{5}{8}$ in. will relieve a large percentage of cases. Those having actual pronation or flat foot may also be further benefited by an arch support inside the shoe, which should include an extension under the first metatarsal if indicated. The arch supports should not be put in without the heel lift. Inside heel lifts may be used in the tennis shoes. If the child is old enough, heel stretching exercises should be given. If the simple measures described in the question fail to give relief, 0.25 to 0.50 gm. of mephenesin orally, either in pills or liquid form, will usually be effective and will permit the child and the family to get some sleep.

Houston 2, Texas.

To the Editor:—*In Queries and Minor Notes, April 28, 1951, the subject of "Leg Pains in Children" was deficient in a number of important conditions. Rheumatic fever, night cramps, and several orthopedic conditions were mentioned as causes. The subject matter would not be complete without inclusion of the following conditions for differential diagnoses:*

1. *Acute infectious lymphocytosis.*
2. *Sickle cell anemia.*
3. *Peripheral neuritis (vitamin B_1 deficiency or other factors).*
4. *Acute poliomyelitis.*
5. *Periostitis due to congenital syphilis ("sabre-shin") and other conditions.*
6. *Coarctation of the aorta.*
7. *Arterial thrombosis due to post-infectious diseases.*

A characteristic feature of these conditions is that they may cause pains in the entire leg or pretibial region.

Brookyn.

PUSTULAR BACTERID

To the Editor.—*I was interested in the query on "Pustular Bacterid" written by a physician in California. This appeared in the April 21 issue of* The Journal, *page 1306. In reading the treatment recommendations I noticed that nothing was said about footwear. Several years ago, a physician had a pustular dermatitis of the feet and hands. He had had a thorough examination for all foci of infection at a nearby medical center. He was able to obtain a pair of vegetable-tanned leather shoes which were free of all rubber, adhesives and the like. Wearing these shoes exclusively brought about a gradual improvement, and today this physician is well. He lost only two weeks from the office and I feel that changing the footwear was instrumental in helping to solve this case.*

VERNAL CONJUNCTIVITIS

To the Editor:—*In answer to the query on vernal conjunctivitis in* The Journal *of April 21, 1951 (page 1305) one must take exception to the statement that "sensitizing agents are almost never found." The causes are generally pollens, dust, or molds. Rarely are foods incriminated. However, in my experience, these cases rarely react to scratch testing. Following negative scratch test reactions, intradermal tests must be carried out with potent extracts. We use pollen extracts in 3% strength (30,000 Noon units per cubic centimeter). The test consists of 0.05 cc. (1,500 Noon units) intradermally. When skin tests are carried out with materials of this strength positive reactions are found in the majority of patients having vernal conjunctivitis. Specific treatment based on such positive skin reactions is usually successful.*

APPLICATION OF PHYSIOLOGIC AND PATHOLOGIC PRINCIPLES TO SURGERY OF THE OVARY

Emil Novak, M.D., Baltimore

The purpose of this paper is twofold. First, it constitutes a plea for the still widely persecuted normal ovary and the essentially normal "cystic ovary." Secondly, it offers for consideration certain pathologic principles that must be envisaged in operations on ovaries that are the seat of definite disease, especially the benign and malignant neoplasms.

NORMAL AND CYSTIC OVARIES

It was in 1872 that Robert Battey, of Georgia, incidentally one of the founders of the American Gynecological Society, instigated perhaps the first serious onslaught on the ovary, which he accused of responsibility for all manner of neuroses and menstrual difficulties. Many thousands of ovaries were sacrificed before this theory was abandoned. The greatly increased knowledge of the biologic importance of the ovary has happily engendered such a high degree of conservatism that no conscientious and well-trained gynecologist of today would treat the normal ovary wantonly.

I am not saying that removal of an anatomically and physiologically normal ovary is never justified, as we all do this in radical operations for uterine cancer. Indeed, some of us believe that there is such a thing as making a fetish of conservatism as in conservation of the ovaries when the uterus is removed because of benign disease at or after the menopause. There are some who urge this plan because they feel that the ovary must have a function even beyond the menopause. I know of no evidence to support this view, while, on the other hand, the postmenopausal ovary is often the seat of neoplastic disease, including even cancer in its usual insidious and highly malignant ovarian forms. We know of no function for the appendix, and yet most of us consider that in the absence of contraindications its prophylactic removal in combination with many pelvic laparotomies is fully justified and to the advantage of the patient. It is usually just as technically easy, and sometimes easier, to remove the adnexa with the uterus as to leave them behind, and my own feeling is that this is a wise and a worth-while prophylactic procedure in women at or beyond the menopause, and that the retention of the ovaries under such conditions would be false conservatism.

I am aware that there are differences in viewpoint on this question, and that there are circumstances in which the local involvement in the pelvis, the general state of the patient, or the patient's psychological, though often mistaken, attitude toward removal of the ovaries under the above-described conditions will influence the wise surgeon to make exceptions. When one attempts to set an age limit beyond which removal of normal ovaries is justified in women still menstruating, one encounters far greater differences of opinion, though approximately 45 years appears to be a popular figure. Here again, one is likely to be influenced by various individual factors, and certainly there can be no criticism of those who prefer to retain at least one ovary in all women who are still menstruating. As a matter of fact, in many women beyond 40, who are still menstruating normally and in whom hysterectomy is necessary, I have often deliberately removed one of the normal ovaries and conserved the other in the belief that one ovary suffices for the endocrine needs of the patient, while the removal of the other divides the hazard of later ovarian neoplastic disease.

However, the chief purpose of this section of my paper is not to preach against conservatism in the treatment of the ovaries, but rather to plead for a scrupulous hands-off surgical policy when the ovary is grossly normal or when it is the seat of minor and usually transient alterations that are apt to be loosely designated as "cystic degeneration." In taking gynecologic histories, one is struck with the frequency of combined appendectomy and resection or removal of a cystic right ovary. I believe that it may be fairly stated that this operation is not as common in the repertoire of gynecologists as it is in that of the general surgeons who perform such a large proportion of the gynecologic operations throughout the country. When such histories are reconstructed, one is likely to find that appendectomy was done, often with an incomplete diagnostic study, that the appendix was found to be discour-

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

agingly normal in appearance, and that the surgeon decided to "fire both barrels of his gun" and to remove the close-by "cystic" right ovary, as well as the appendix. To compound his error, the surgeon not infrequently thus removes two innocent organs instead of one, overlooking such real causes of pain as right urinary tract disease or functional gastrointestinal disorder.

With rare exceptions the cystic ovary should receive the same surgical respect as one that appears entirely normal. There are few ovaries that do not show at least some tiny cysts, representing nothing more than the blighted, atretic follicles that come and go from month to month throughout the functional life of the ovary. Even when the ovary is studded with these tiny cysts, there is no reason to suspect it of responsibility in the production of pelvic pain, especially in the absence of inflammatory pelvic disease. With the latter, one may see more serious degrees of cystic change, especially when the ovaries are matted beneath dense adhesions that conceivably might make rupture of mature follicles difficult. Still other types of cystic ovary are seen, such as those in which the ovarian condition is merely a local expression of endocrine dysfunction, of either ovarian or pituitary origin, as in certain cases of functional bleeding. However, these types are less likely to be the object of direct surgical attack and need not be included in this discussion.

At times one or more of the atretic follicles may, for some unknown reason, become extremely hydropic, giving rise to follicular cysts that may attain a diameter of many centimeters. Even these tend toward resorption and ultimate disappearance, but during their lifespan they produce distinctly palpable ovarian enlargement and, in the occasional case, pelvic discomfort, and, rarely, may be complicated by torsion of the pedicle. Gynecologists are in agreement that small palpable cysts of the ovary are in general to be treated expectantly, simply because of their tendency to spontaneous disappearance, with not infrequently a reappearance of similar functional cysts in the same or opposite ovary. The patient is exposed to no hazard by this expectant plan. If however, the cyst grows steadily larger from month to month, operation is advisable because of the reasonable certainty that a genuinely neoplastic cyst is presented. When moderate-sized follicular cysts are encountered at operation for other conditions, simple needling of the cyst hastens its resorption and is generally preferable to excision of the cyst. The old dictum that an ovary should be either left alone or removed entirely is no longer acceptable; there is, nevertheless, a large nugget of truth in it. Whenever partial resection of the ovary is done, as in the removal of large follicular cysts, small dermoids, or small localized areas of endometriosis, there is a hazard of such sequelae as intestinal or omental adhesions or tubal angulation, no matter how careful the surgeon may be not to leave any raw surfaces.

What to do about the ovaries is often a difficult problem in cases of endometriosis, and only a somewhat less difficult problem in cases of inflammatory pelvic disease. The greater importance of this question with endometriosis is due to the fact that the condition is under the physiological control of the ovaries. Radical removal of all ovarian tissue is fully justified and strongly advisable in the minority of cases of very extensive endometriosis in which both ovaries are seriously involved, as well as adjacent organs, such as the rectum and sigmoid. Fortunately such cases are less likely to be encountered among patients of the younger group than among those approaching middle life, on whom the sacrifice of the reproductive function has already been inflicted by the disease; the sacrifice of endocrine function is often a modest price for such patients to pay for relief of their symptoms. There is no longer a place for the extensive and hazardous resections that were at one time recommended for the widespread infiltrations of the rectum and sigmoid in some of these cases, although colostomy is in rare cases necessary because of existing or impending obstruction. Removal of all ovarian tissue brings about regression of the endometriosis and also of the patient's symptoms. When, as is true of an occasional case, the removal of all ovarian tissue is technically impossible, postoperative irradiation will accomplish the desired abolition of ovarian function.

Far more frequently, however, the endometriosis is of much more moderate extent and there is now little difference of opinion about the wisdom of conservative plans of surgical treatment adapted to the findings in the individual case, but with always the end object of preserving the endocrine and reproductive functions. Even when one ovary must be removed because of a large endometrial cyst, the excision of a smaller endometrial cyst in the other ovary is preferable to bilateral oophorectomy. Associated lesions of the uterosacral ligaments may be treated by cautery destruction or local excision, but the latter may be difficult and admittedly sometimes incomplete. Yet the patient is likely to be relieved of her symptoms, especially if presacral neurectomy is also carried out when dysmenorrhea has been severe.

One cannot argue that the lesion is always completely eradicated by such conservative operations, or that there is not a possibility of its later resurgence, with the necessity of further operation. However, the incidence of this sequence is far less than might be imagined, while, on the other hand, the fairly frequent occurrence of subsequent pregnancy has been noted in all the statistical studies that have been made. I am sure that every gynecologist always has under his care a certain number of patients in whom he is sure a primary or a residual postoperative endometriosis is present, but with no symptoms or with easily tolerable symptoms. Expectant or simple palliative treatment of such patients is to be preferred to operation, just as one would ordinarily abstain from operating on patients with such clearly palpable evidences of chronic inflammatory pelvic disease as adherent and enlarged ovaries, when these occur with few or no symptoms.

A word may be interjected here in behalf of the usually normal tubes encountered in association with endometriosis, and also the frequently normal ovary seen in cases of chronic salpingitis. It is often advisable to conserve such normal organs, since the later development of serious pathologic involvement on the other side may make reoperation necessary. I have often wished for such a spare ovary when removal of the remaining ovary was necessary in patients who had previously been operated on for tubal pregnancy on the contralateral side, and in whom the surgeon had unwisely and usually thoughtlessly removed a good ovary with the pregnant tube.

OVARIAN NEOPLASMS

What has been said thus far has applied to the surgeon's proper attitude toward ovaries that are anatomically entirely normal or that at most display relatively harmless departures from the normal. The ovary is often the seat of definite and sometimes grave pathologic involvement, especially of neoplastic type. In these cases the surgeon is often posed with difficult problems of the scope and extent of the operation that should be done in the best interests of the patient. It is clear that the surgeon who knows something of the gross characteristics and the pathologic potentialities of the various ovarian neoplasms has an advantage over the one who does not. On the other hand, the most pathology-minded surgeon, or even the one who can have at his elbow the most expert pathologist, is not always certain to make the right decisions. The frozen section as an aid to operating-room technique has some value but also definite limitations, and I for one have depended on it much less than on the gross characteristics of the ovarian lesion. Only a few of the more important problems that arise in this field can be touched on in this paper, and probably most conveniently by discussing surgical principles as applied to the major tumor groups.

Cystadenomas of Ovary.—It is not always possible from the external or even the internal appearance of a cystadenoma of the ovary to be sure whether the neoplasm is of pseudomucinous or serous type, or whether both varieties are represented in the ovary, as occasionally happens. However, certain generalities in regard to the management of neoplastic cysts may be profitably discussed.

If a large unilateral ovarian cyst shows a smooth outer surface, a thin or at times an almost translucent wall, and if on being opened it shows many locules and no papillomatous excrescences, it is likely to be of benign pseudomucinous type and can be safely treated by unilateral adnexal removal. It must be remembered, however, that even the histologically benign pseudomucinous epithelium of such cysts is capable of implantation on the peritoneum if disseminated through rupture of a cystic locule, giving rise to the rare but usually ultimately fatal pseudomyxoma peritonaei. This is the basis of the general practice among gynecologists of trying to remove such cysts intact, even when very large and when their removal without preliminary trocar drainage involves a very long incision. In some cases extensive and firm adhesions make this impossible, and in these the trocar decompression of the cystic mass must be carried out with proper precautions against peritoneal contamination, such as adequate packing-off, placing of a purse-string suture around the cannula, and drawing the point of puncture of the cyst wall outside the abdominal wall as soon as the cyst is sufficiently collapsed. This is not to say that peritoneal contamination with the fluid of such cysts will inevitably be followed by peritoneal implantations; for pseudomyxoma peritonaei has always been rare, in spite of the fact that accidental contamination of the peritoneum has certainly often occurred, and the gynecologists of a former day rather generally practiced decompression of large cysts. We can only speculate about the determining factors of this condition, but there seems to be no question of the advisability of avoiding peritoneal contamination in such cases. Again, we must not forget that a cyst that appears to be benign may be undergoing carcinomatous change somewhere in its wall, and that genuine peritoneal carcinomatosis may thus occur instead of the implantation of benign epithelium.

It seems advisable to emphasize here a point that I believe to be an important one. I refer to the wisdom of opening every cyst immediately after its removal, before the abdomen is closed. I shall have occasion to stress this point with regard to the solid or semisolid tumors of the ovary. A cyst that because of its smooth and thin wall looks innocent may, on being cut into, show, perhaps in a localized area, a mass of papillary or fungoid appearance or a hard nodular mass or a mass or nodule of fine-meshed spongy appearance. The discovery of such areas must at once sound the alert, and I believe that most of us would feel safer to make the operation a radical rather than merely a unilateral one. In some cases a frozen section may be helpful, but a report is not always quickly obtainable, and, even if it is it is all too frequently not decisive. All too often the surgeon who removes a large cyst intact wants to keep in intact until he gets a photograph or a drawing, or shows it with pride at the next staff meeting. But if he keeps in mind only the best interests of his patient, he will have the cyst opened immediately after its removal, so that it can be more intelligently evaluated by himself or by his pathologist colleague.

The papillary type of cyst, usually of serous character, presents the most difficult problems of surgical judgment. Undoubtedly, this group is possessed of far greater and more wicked potentialities than is the pseudomucinous type, which is usually nonpapillary. Naturally and properly, therefore, the attitude of most gynecologists toward papillary cysts is likely to be much more radical than toward the nonpapillary group. No one can assume an oracular role in outlining the surgical policies to be pursued, for many tumors of the papillary group exhibit clinical vagaries that make prognosis difficult.

A few general statements can be offered for consideration and discussion; but, before I embark on this, it should be emphasized that not only the clinician, but also the pathologist in his interpretation of the microscopic picture of tumors of this group, must recognize the difficulties of prognosis. For example, the pathologist does not hesitate to report that certain tumors are histologically entirely benign, but can he in such cases assume that the patient may not return with a peritoneal recurrence? He will be the first to emphasize that he cannot make this assumption without error in at least a small proportion of cases. Again, he will have no doubt in diagnosing many tumors as both histologically and clinically malignant. However, in an inevitable proportion of cases he cannot be too certain of even the histologically benign and histologically malignant, and he is likely to find differences of opinion among other pathologists to whom he refers his sections.

This digression on pathology is justified simply because it emphasizes the difficulties and the seriousness of the surgeon's problem in such cases, his decisions being necessary even before the results of complete pathologic study are available. As a matter of fact, in some cases the scope of the operation and the decision whether it should be conservative or radical are influenced by weighing one factor against another. The surgeon has to consider the age of the patient and the importance or unimportance of preserving the reproductive function against the possibility of future hazard to his patient if, on the basis of his evaluation of the tumor, a conservative operation is done. This method seems to make him something of a scientific gambler, but he should not make a great many mistakes if he has some knowledge of the gross pathologic characteristics of tumors of this sort.

In the case of a patient of the younger group, in which the surgeon would of course like to be conservative if possible, if an ovarian cyst, on being opened, shows a number of discrete and not very exuberant papillary ingrowths and if the other ovary is entirely normal, simple unilateral removal is fully justified, with ordinarily no unpleasant repercussions. Even if a few warty outgrowths are seen on the outside of the cyst, a similar plan can be followed. These do not indicate malignant penetration of the papillary growth but are produced merely by the manner of development of the tumor, representing a combination of surface papilloma and serous papillary cyst. As a matter of fact, the solid papillary portion may greatly dominate the picture and may be present in the entire absence of any cyst formation.

It is difficult to explain why such exuberant external papillomas may be present without peritoneal implantation, while with at least some histologically benign papillary cysts such implantation may occur. I recall a patient whose whole pelvis was filled with an enormous bilateral papillary ovarian growth that infiltrated surrounding organs and that could literally be scooped out by the handful. It was certain, therefore, that in spite of the radical operation that was done, innumerable tumor cells must have been left. And yet this patient has remained perfectly well for more than 25 years.

The fact remains that when a cyst is filled with large masses of this papillary material, often necrotic, it is likely to be malignant and certainly should be treated accordingly.

Solid and Semisolid Tumors.—When one comes to solid or semisolid tumors of the ovary, some knowledge of gross pathology is again of value, with again an inevitable possibility of error. Fibromas and Brenner tumors are usually readily recognized by their sharp circumscription and by the whitish or slightly yellowish appearance of the homogeneous-appearing cut surface.

In all but a small proportion of the solid or semisolid forms of carcinoma, a presumptive gross diagnosis can be made. There are certain solid types, it is true, in which mistakes can be easily made, as in the scirrhous carcinoma or even the unilateral Krukenberg tumor, either of which can be mistaken for fibroma.

The mention of Krukenberg tumor is a cue for emphasizing the importance of careful palpation of the abdominal organs, especially the stomach, in all cases of tumors in which malignant change is suspected. Not only may the primary tumor be revealed, but also the presence of metastasis in the liver, omentum or parietal wall may be determined.

Unfortunately, the malignant nature of many solid or semisolid ovarian tumors is at once obvious enough because of the infiltration of surrounding tissue, the granularity, friability, and often necrosis of the tumor tissue, and very often the presence of extensive peritoneal metastasis. In the less advanced cases of unilateral tumors, either solid or semicystic, which are still well encapsulated, one need not make many mistakes if one bears in mind the fact that such tumors ordinarily have the tissue characteristics that were mentioned above for the more advanced infiltrating growths.

While radical operation is the desideratum in malignant ovarian growths, it is unfortunately impossible in a large proportion of cases because of the already widespread dissemination of the disease. Even in the presence of peritoneal or visceral metastases, removal of the primary growth is advisable if this is technically possible without too great a hazard, as gynecologists are fairly well agreed that removal of the primarily involved ovaries does appear to have a definitely retarding effect on the course of the disease. Incidentally, the presence of ascites and hydrothorax does not justify the conclusion that a solid tumor of the ovary is malignant, but a roentgenogram of the chest is always advisable when malignant change is suspected.

With regard to the less common types of ovarian malignant growths, such as the granulosa-cell carcinoma and thecoma, dysgerminoma, or arrhenoblastoma, one will often be alerted to them by the age of the patient and the biological effects produced by the functioning group. The possibility of dysgerminoma should always be envisaged in tumors in young girls, but there are other possibilities, such as teratoma and sarcoma. The granulosal tumors of young girls often reveal themselves in the precocious puberty syndrome that they produce at this age. In any of the dysontogenetic group of tumors, when encountered in early life, conservative unilateral operation is fully justified if, as is most usually the case, the tumor is of small or moderate size and if it has not broken through the capsule and infiltrated surrounding tissues. To say that recurrence and metastasis cannot occur would be incorrect in the light of the many reports in the literature to the contrary, but the hazard is numerically not sufficiently great in cases of the type described above as to justify routine radical procedures. The granulosothecal group of tumors occurs most frequently in middle or late life, and, although the degree of malignant involvement with this type is definitely less than with the commoner ovarian cancers, I believe that at these age periods they should call for radical operation. I have always felt that most pathologists take these tumors much too lightly, and that metastasis and recurrence, sometimes early, but often very late, occur much oftener than is generally believed. It is my impression that the study of the steadily growing material of the Ovarian Tumor Registry will confirm this belief.

There are many gaps in the above discussion of the surgical physiology and surgical pathology of ovarian neoplasms, but even this necessarily brief consideration will, I hope, emphasize the clear advantage to the surgeon of training himself to be his own operating-room pathologist. The next best thing is to have at his elbow a competent pathologist, but this is not always possible, nor are all general pathologists highly trained in the rather special field of gynecologic pathology. *The gyne-*

cologist who is unhappy if he cannot follow his material through the pathologic laboratory will acquire an increasing knowledge of correlated gross and microscopic pathology. This gives him increasing confidence in the decisions he must make at the operating table, besides adding to his daily work a zest and scientific enthusiasm that his more mechanistic confrere can never enjoy.

ABSTRACT OF DISCUSSION

Dr. Ludwig A. Emge, San Francisco: The essayst will forgive me for not sharing his belief that the ovary is of little consequence during the menopausal years. This period of a woman's life is an uncertain time quantity, and here in California, where menopause occurs most frequently at 50 yr. or over, the casual removal of the ovaries at hysterectomy done for purely uterine causes in the middle forties, just because that period is considered the traditional age of menopause, is not warranted. The assumption that removing just one ovary will reduce the incidence of cancer by 50% unfortunately is defeated by the law of probability, since ovarian cancer occurs bilaterally in 50%, and, when it occurs unilaterally, it has no choice of location. I doubt that the protective value of such a prophylactic approach would yield more than a bare 10% probable safety factor against a cancer that is relatively rare. This does not justify the casual sacrifice of thousands of normal ovaries. I have never seen cancer of the ovary after hysterectomy except in a few instances in which the appearance of the cancer warranted the conclusion that the disease had been overlooked at the time of operation. If one ovary is good enough to remain with the host, why not both? I see no parallel between so-called prophylactic appendectomy and casual oophorectomy. I am afraid of such a philosophy because it encourages unnecessary surgical intervention. We do not apply such a principle to any other vital organ. There is no objection to the removal of advanced senile ovaries, but many are left behind in vaginal hysterectomies in old women, and no harm ensues from doing so. In regard to the treatment of cancer of the ovary, I should like to plead for two procedures that have been of great help in palliation, as well as cure, on one hand and of inestimable value in evaluating the extent of the disease on the other. Not infrequently pathologists find it difficult to determine with finality the true nature of cystic ovarian neoplasm. I have for years taken free fluid from the abdomen as soon as the abdominal cavity has been opened, for the purpose of ascertaining the nature of the cells in the abdominal fluid. The presence of malignant cells can be determined almost as quickly and reliably as with a biopsy. The same holds true of the study of the contents of cysts. Today, with the steadily improving cytologic smear facilities, this procedure is now more feasible than ever to prognosticate subsequent events. A second plea is to desist from immediate surgical intervention wherever the operability of a malignant ovarian tumor is in question. Obtain free fluid for study, or obtain a metastatic nodule if it exists, but do not make a biopsy of the tumor proper solely for academic reasons. Close the abdomen, and let the radiologist take over. Should the tumor shrink, it is often possible to remove the malignant mass relatively easily after the skin has recovered. Not only has palliation in my hands improved immediate results materially, but five-year survivals have come up from 18 to nearly 30%.

Dr. Lyman W. Mason, Denver: If there is one part of Dr. Novak's paper to which I should like to add my emphasis, it is that which has to do with the frequent surgery done on the physiologically normal ovary. This consists in the removal of normal follicles, normal corpora lutea, and simple retention cysts, even though of considerable size. He also called attention to the seeming preponderance of "cysts" in the right ovary. It took me some years to realize that this seemingly increased susceptibility of the right ovary to pathologic changes, usually "cysts," was dependent on the fact that the right ovary was accessible through an appendectomy incision, while the left usually was not. Thus, by a distance of 7 or 8 in. (18 or 20 cm.), the left ovary usually escaped damage. I agree with Dr. Novak that "there is a large nugget of truth" in the dictum that an ovary should be either left alone or removed entirely. Ovaries do not stand too much interference in their circulation. It is a mistake to leave a very small portion of one ovary when extensive pelvic surgery has been performed. Such pieces become incarcerated in scar tissue or embedded in the posterior surface of the broad ligament, with the production of menometrorrhagia and/or pain, necessitating subsequent operative procedures. Surgical intervention is not indicated when the ovary is only moderately increased in size, when it is not progressively increasing in size, when the patient's menstrual periods are within normal limits, or when the enlarged ovary is not producing other symptoms. If left alone, most of these enlargements will eventually disappear. I have cured many more cases of menstrual abnormalities with the use of thyroid than I have with ovarian surgery. There is a laudable growing interest in conservative surgical treatment of endometriosis, especially in the interests of fertility. I agree that there is no reason to leave the ovaries in any woman over the age of 45 when pelvic surgery is done, since they have, or have about, reached the end of their span. In women between the ages of 40 and 45, it is my practice to leave those ovaries that are not pathological, since many women do not cease to menstruate until between the ages of 50 and 55, and in women under the age of 40 to leave all those in which the visible pathologic change is minor. I agree with what Dr. Novak has said about the surgery of ovarian neoplasms, those definitely malignant, as well as the pseudomucinous cysts and serous cystadenomas. Dr. Novak did not mention the seemingly extensive involvement that may appear in ovaries in connection with hydatidiform mole and corionepithelioma. I am sure that the surgical measures of many who do pelvic surgery would be much more conservative if their testicles were involved rather than their patient's ovaries.

Dr. Emil Novak, Baltimore: On all points except one Dr. Emge and I are apparently in full agreement. My paper has included a plea for conservatism in ovarian surgery for benign lesions during reproductive life. On the other hand, when hysterectomies are done in menopausal and postmenopausal women, it is my belief that it is false conservatism to retain the ovaries. So far as I know, no one has ever shown that these organs, so important during reproductive life, are of any functional importance after the menopause. Moreover, while I agree with Dr. Emge that carcinoma in such residual ovaries is rare, there are few of us who have not at times been obliged to reoperate because of other lesions, chiefly cystic and at times cystadenomatous. The removal of the ovaries at the times of hysterectomy is ordinarily just as easy as the hysterectomy alone, sometimes easier, and it is likely to leave a cleaner and better peritonealized pelvis. It would be foolish to set arbitrary age limits beyond which the complete operation is to be performed, and individualization must be practiced here as in all surgical problems. In the occasional woman, usually one with wrong ideas concerning the effects of ovarian removal at this age, the surgeon had better leave one or both ovaries to avoid any psychologic repercussions. As a rough working rule, the age of 45 would probably be considered a fair point of departure, although exceptions in either direction can properly be made.

Balanced Anesthesia.—The modern trend in anaesthesia is toward the employment of small doses of various drugs which may be given by several routes and excreted in different ways. This "balanced anaesthesia," as it is called, is another method of attempting to obtain the ideal. The argument is presented that small amounts of many agents are less toxic to the patient than a large amount of a single agent. The safety factor to the patient is widened, and the balanced anaesthesia induced keeps him close to the physiologic normal during operation. These trends are a healthy sign in the specialty. They indicate that the anaesthetist, unlike his patients, is not sleeping quietly, content with the knowledge which has been accumulated. He is looking forward and upward, in the realization that only the fringe of potential possibilities has been explored.—C. R. Stephen, M.D.C.M., and H. M. Slater, M.D., *Anesthesiology,* March, 1951.

PILOT STUDY OF MATERNAL AND NEONATAL FACTORS IN PREMATURE INFANT MORTALITY

Helen M. Wallace, M.D., New York; Henry Rascoff, M.D., Brooklyn
and
Hilda Knobloch, M.D., New York

Since premature birth is the largest single cause of infant and neonatal mortality[1] nationally as well as locally in New York City, it is evident that further significant reduction in these mortality rates will be achieved only by the prevention of premature birth and by the provision of better pediatric and nursing care for the prematurely born infant. Significant reduction of maternal mortality has occurred to a great extent as a result of intensive studies which medical and public health groups have conducted of individual maternal deaths and as a result of the application of the knowledge thus acquired. It is reasonable to expect that a comparable method, if applied to deaths among prematurely born infants, might accomplish similar results. Therefore, a pilot study of a sample of deaths among prematurely born infants in Brooklyn was undertaken jointly by the Child Health and Welfare Committee of the Kings County Medical Society and the Maternity and Newborn Division of the New York City Department of Health.

METHOD OF STUDY AND SAMPLE STUDIED

Death certificates were obtained for all premature infants (those born alive weighing 5½ lb. [2,500 gm.] or less at birth) who died during the month of February 1949, before reaching their first birthday. A special form was prepared for the study, which included detailed questions regarding the antepartum, labor and delivery course of the mothers, as well as the condition and care of the premature infants in the delivery room and nursery. The hospital clinical records of the mother and infant and autopsy reports were reviewed by a pediatrician, the available information recorded on the study form, and the data tabulated. As the data are presented, it will be apparent that not all hospital records contained the necessary information. Yet, valid information in many important areas of care can be presented.

During February 1949, 55 premature infants died in Brooklyn. This figure represents approximately one-twelfth of all annual premature infant deaths and 1% of all annual premature infant births in Brooklyn. Two infants were excluded from the final tabulations because death occurred at four and one-half months of age from causes apparently not related to prematurity. One infant died at home after a fracture of the right femur and ensuing bronchopneumonia due to a fall from bed. The second infant, gaining well for two months after discharge from the hospital, was admitted three days after the onset of an acute upper respiratory infection and died four days later of lobar pneumonia.

The remaining 53 infants died in 24 different hospitals in Brooklyn. All except five deaths occurred in the hospital of birth. Two infants were born at home and transferred by ambulance to hospitals one hour after birth. A third infant was discharged from the hospital of birth at 6 days, admitted to the hospital of death at 12 days, and died on the 15th day. A fourth infant was discharged from the hospital of birth at 7 days, admitted to the hospital of death at 31 days, and died on the 66th day. A fifth infant, weighing 794 gm., was transported from the hospital of birth by the Special Premature Transport Service of the New York City Departments of Health and Hospitals at 47 hours of age; he died 7 hours after transport. Forty of the 53 infants were white.

PERTINENT MATERNAL FACTORS

There were 50 mothers of this group of 53 infants, of whom 44% (22) were primiparas; the parity in this series is the same as that of all women delivered in New York City. Other previous studies[2] indicate a high incidence of premature birth in women in their first pregnancy. The 28 women who had had previous pregnancies had delivered 24 full-term, 20 whose status is unknown, and 13 premature infants—at least one out of 4.5 previous pregnancies had terminated prematurely.

Of this group of 50 mothers where the nature of the antepartum care was stated, approximately 50% (24) were private patients and 25% (13) were general service patients. Five women had had no antepartum care. In only 17 instances was any detailed information about the antepartum course recorded.

Taylor and his co-workers[3] have shown that when the mother has a serious medical or surgical complication, the premature infant mortality rate is four to five times that of infants born of healthy mothers. Thirty-eight per cent (19) of the mothers in this series had complications of pregnancy which may have played a role in premature labor and delivery, either because they necessitated early termination of pregnancy or because they indicated interference with the nutrition of the fetus. Included were cases of bleeding, toxemia, ruptured appendix, and malnutrition.

It is well accepted that women who are in premature labor should receive no analgesia[4] in order to protect the respiratory mechanism of the fetus. Certainly morphine is usually considered to be the most depressant of all analgesic agents. In this sample, the mothers of almost 50% (23) of the infants received some type of analgesia, including the mothers of 6 infants who received morphine (table 1).

Similarly, it is generally accepted[5] that women in premature labor should not receive a general inhalation type of anesthesia because of the anoxia produced. It was not possible to administer an anesthetic to the mothers

---

From the Maternity and Newborn Division, New York City Department of Health, and the Child Health and Welfare Committee of the Kings County Medical Society.

Although this report is being presented by three pediatricians, it could not have been prepared without assistance from the allied fields of obstetrics and nursing, and we wish to acknowledge the valuable consultative advice which we received.

Chief, Maternity and Newborn Division, New York City Department of Health (Dr. Wallace); Chairman, Child Health and Welfare Committee, Kings County Medical Society (Dr. Rascoff), and Pediatric Consultant, Maternity and Newborn Division, New York City Department of Health (Dr. Knobloch).

of 8 infants because they precipitated in bed or delivered at home. Almost 30% (13) of the remaining 45 infants were subjected to the possible adverse effects of inhalation anesthesia (table 2).

It is generally felt by obstetricians that because of the fragility of the vascular system and the tendency toward hemorrhage, premature infants should be delivered by low forceps immediately after full dilatation of the cervix when the head is on the perineum; certainly a second stage of labor longer than 30 minutes is not desirable. In this series, the mother of 17% (9) of the infants remained in the second stage of labor for from 30 minutes to 2 hours.

* Two home deliveries.

It is well known that breech presentation [6] and cesarean section carry a higher neonatal mortality than does vertex presentation but that additional factors other than the method of delivery influence the survival rate in cases of premature labor. Acken [7] has shown that there has been a marked decrease in the maternal mortality rate following cesarean section without any comparable decrease in fetal mortality rates and that prematurity is the most frequent cause of the fetal mortality. One might conclude that section should be performed for maternal indications, but that it does not offer any advantages if performed for fetal indications alone. In this series, 14% of the babies were delivered by cesarean section and 6% by breech extraction. The over-all incidence of cesarean sections in New York City is 3.6%.

It is strongly recommended by most obstetricians that episiotomy be used at the time of delivery; low forceps is almost as widely accepted as a necessary procedure. In only 25% of the instances in which it was possible was episiotomy performed or low forceps used. A combination of the two procedures was used in only 20% of the possible cases (table 3).

CARE OF THE PREMATURE INFANT IN THE DELIVERY ROOM

Obstetric, pediatric, and anesthesiology authorities are becoming increasingly aware of the importance of resuscitation as a lifesaving measure in the delivery room when spontaneous respiration is delayed. The Kings County Medical Society [8] has recently issued an excellent guide on the preventive and therapeutic methods of management of asphyxia neonatorum. No information was recorded in the clinical records about spontaneous respiration in 51% (27) of the infants, or about the use of resuscitation in 38% (20). It was stated that 22% of the infants breathed spontaneously. Resuscitation of varying types (intratracheal or nasopharyngeal aspiration with or without oxygen, given directly or under positive pressure) was used for 40% (21) of the infants, including two who breathed spontaneously (table 4).

One of the cardinal principles in the care of the premature infant is that the infant must be assisted in maintaining respiration. It has been shown that supplying oxygen may change the periodic type of respiration, frequently seen in premature infants, to a regular pattern.[9] Most pediatric authorities agree that oxygen should be provided continuously from birth for at least 24 hours, *particularly for small premature infants.* Only 13% (7) of all infants received oxygen continuously in the delivery room, and an additional 20% (10) received it only in the course of resuscitation. Of those 19 infants who were stated to be cyanotic at birth, 63% (12) received oxygen, either continuously or during the course of resuscitation (table 5). As would be expected, there was an inverse relationship between birth weight and tendency toward cyanosis, and all 7 premature infants who received oxygen continuously in the delivery room weighed less than 1,500 gm.

and oxygen in the transfer of the infant from the delivery room to the nursery.

Because the premature infant is physiologically unequipped to withstand changes in external environment, it is well accepted that means of controlling environmental temperature and humidity must be supplied. Only 10% (5) of the infants were stated to have been provided with heat in the delivery room.

TABLE 5.—*Correlation of the Presence of Cyanosis with Administration of Oxygen in the Delivery Room*

CARE OF THE INFANT IN THE NURSERY

To complete the picture of the use of the heat and oxygen, oxygen was supplied to 96% and heat to 80% of the 49 infants who survived to reach the nursery. Although this finding is in contrast to the recording in the delivery room, there was a delay in the provision of these necessary adjuvants in approximately 20% of the cases (table 6). This delay varied in time from one hour to 34 days, and in four cases it was given just prior to death.

Although the scientific value of the use of vitamin K in the prevention of hemorrhagic manifestations is not proved, nevertheless, many obstetric and pediatric authorities recommend its routine use for women in premature labor, or for premature infants immediately after birth. In 33% of the cases, neither mother nor infant received vitamin K.

Proper feeding is one of the most important aspects of premature infant care. Some of the factors to be considered are the period of starvation prior to initial feeding, the method of feeding, reactions to feeding, and the training of the personnel who feed the infants. In the final analysis, the time of initial feeding depends on the clinical evaluation of the individual infant. It is generally accepted, however, that time for rest, for the establishment of an adequate swallowing reflex, and allowance for homeostasis are more important than the provision of calories in the first days of life of a small premature infant. Many pediatric authorities feel that for these reasons it is safer to wait 24 to 48 or even 72 hours prior to feeding an infant weighing less than 1,500 gm. at birth and that certainly no premature infant should be fed prior to 12 hours.[10] The period of initial starvation varies inversely with the birth weight.

* An additional 4 babies died in delivery room.

One infant weighing less than 1,000 gm. at birth, 2 in the 1,000 to 1,499 gm. group, 1 in the 1,500 to 1,999 gm. group and 3 in the 2,000 to 2,499 gm. group, or a total of 7 infants, were fed within the first 12 hours after birth. Thirty infants died before feeding was initiated (table 7).

All varieties of methods were used for the 23 infants who were fed—gavage, dropper, Breck feeder and nipple, alone or in combination. A Breck feeder, which most pediatric authorities feel may be a serious hazard from the viewpoint of aspiration, was used in three instances. Although it was not possible in most instances to tell from the records whether the infants were held or supported when fed, personal observations have shown that the propping of bottles, even for premature infants, is not an uncommon practice.

An important clinical guide in planning the method of feeding of premature infants is the infant's reaction to feeding. Of the 23 infants who were fed, approximately 50% had regurgitation and cyanosis following feeding. No information on these points was given for another 40%. The frequency of these reactions varied from after one feeding to after all feedings. It seems reasonable to suggest that, because of the relatively high incidence of unfavorable reactions to feeding, more judgment must be used in selecting the method of feeding for each infant, and the skill of the personnel who do the feeding must be carefully scrutinized.

TABLE 7.—*Birth Weight Correlated With Time of Initial Feeding*

Time of Initial Feeding	Birth Weight, Gm. Not Weighed	Less than 1,000	1,000-1,499	1,500-1,999	2,000-2,499	Total

	3	18	13	9	10	53

It is generally agreed by pediatricians that nursing skill is one of the most important factors in the feeding of premature infants, as well as in their general care. In this series, a wide variety of nursing personnel and, at times, medical personnel fed these infants. Included were registered nurses, practical nurses, student nurses, hospital attendants, pediatricians and house staff members. Of all the individual members of the nursing personnel who fed premature infants, only one had had advanced training in the care of premature infants at the time these infants received care.

There were 186 nurses who gave care to this group of 53 premature infants; 63% were registered professional nurses, 23% were practical nurses, and 6% were student nurses. It is interesting to note that 50% of the registered professional nurses worked in 4 of the 24 hospitals. More important, eight infants received their complete care from practical nurses. It was found that care was

---

10. Gordon, H. H.: Feeding of Premature Infants, Am. J. Dis. Child. 73:713 (June) 1947.

given wholly by practical nurses to an additional four infants on one tour of duty and to an additional two infants on two tours of duty.

Just as skilled nursing is necessary in the care of premature infants, so too is skilled pediatric supervision. Seventy-five per cent of the 27 infants who were under the care of an attending physician were supervised by a pediatrician. Twenty-four infants were under the care of house staff almost exclusively from the pediatric service. In other words, 80% (43) of the infants were under some type of pediatric supervision (table 8). Of the two infants who had no medical care, one died in the delivery room immediately after birth. The time after birth when the infants were seen by an attending pediatrician is likewise of importance. Half were seen by an attending pediatrician in the infant's first 24 hours of life. The other half were seen for the first time by attending pediatricians from the second to the tenth day of life.

AGE AND CAUSE OF DEATH

It is well known that the first 48 hours of life are the critical period for the premature infant. The infants in this series show little deviation from the usual pattern. Fifty per cent of the infants who died did so in the first 24 hours, and a total of 86% died in the first week. Only 3 of the 34 infants weighing less than 1,500 gm. at birth who died survived the first week, while 25% of the larger infants lived longer than seven days (as shown in the chart, where the solid column represents infants who weighed over 1,500 gm. at birth and the stippled column represents infants who weighed under 1,500 gm. at birth). As would be expected, 40% of the deaths occurred in infants weighing less than 1,000 gm. at birth. Approximately 20% of the remainder of the deaths occurred in each of the other three birth weight groups (table 9).

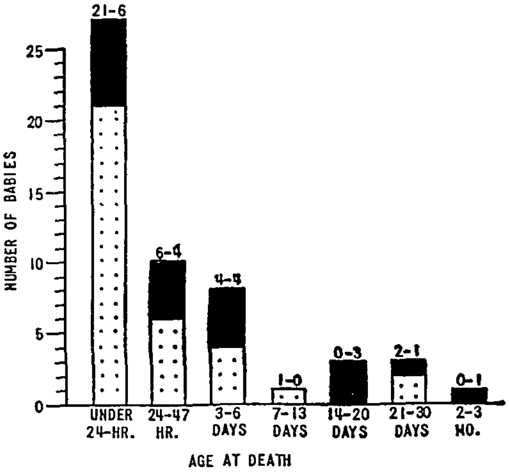
* One infant in each group died in delivery room.

Obviously, one of the points of greatest interest to clinicians is the specific cause of death in this group of premature infants. There were three sources of information on cause of death: the autopsy report, the clinical record of the infant in the hospital, and the death certificate.

Autopsies were performed on 29 of the infants; 60% were done by pathologists, and the remaining 40% by residents in pathology. Seven autopsies were incompletely done. No clinical diagnosis was recorded on the hospital record of 12 infants.

Death was attributed to prematurity alone in over 40% of the cases on the death certificate and in the clinical records, while some other cause was found in all instances when an autopsy was performed. Death was attributed to cerebral hemorrhage in a significantly higher percentage of cases in which an autopsy was done (26% as compared with 7 and 8%), while some abnormality of the respiratory tract was listed with equal frequency in the three sources of information. It is significant that following autopsy over 60% of the respiratory deaths were found due to aspiration pneumonia. Prematurity and congenital atelectasis formed the largest single group on the anatomical reports (table 10).



Age at death of premature infants. Stippled columns represent numbers of infants whose birth weights were less than 1,500 gm.; solid columns, infants whose birth weights were more than 1,500 gm.

Of further interest to both clinicians and public health workers is the degree of correlation of information regarding the cause of death between the autopsy report, the clinical record and the death certificate. Since information on the death certificate is usually derived from data on the clinical record, there was a high degree of correlation between these two sources of information (65% complete and 25% partial correlation). For the reason just cited, other comparisons represent substantially a correlation of clinical and anatomical diagnosis and they are all proportionately the same. There is no correlation in 40% of the cases, with 30% complete and 30% partial correlation. (Table 11 shows these correlations, where sufficient data were available to make them.) The fact that prematurity with congenital atelectasis only is listed as the cause of death in such a high proportion of the autopsy protocols indicates that either there was no demonstrable cause of death, or that the caliber of the autopsy was such that no cause was found.

COMMENT

After presentation of these clinical data on this series of premature infant deaths, one might logically ask "What are the lessons to be learned and what are the next steps to be taken?" Beck [11] in 1941 reported on the role of the obstetrician in the prevention of premature birth and in the prevention of death in premature infants. Recent studies stressing the influence of antepartum nutrition on the status of the infant at birth and emphasizing antepartum care indicate a potential approach to the prevention of premature birth. Beck and others have also stressed the importance of the management of the pregnant woman with complications. The King County Medical Society Committee on Maternal Welfare [12] has drawn up an excellent set of recommendations for the care of antepartum patients. Consideration must also be given to the use of episiotomy and outlet forceps in the delivery of the infant and the use of vitamin K. The Denver group has recently reported on the importance of nonuse of analgesia and inhalation anesthesia for women in premature labor. It is evident, therefore, that there is a gap between available scientific knowledge and present day obstetric practice.

So, too, there is a gap in the application of the available pediatric knowledge of the care of the premature infant in the delivery room, in transfer from delivery room to nursery, and in the nursery itself. It seems clear from the material presented that there must be wider dissemination of knowledge regarding the value of proper means of neonatal resuscitation as a lifesaving measure, followed by the training of physicians, including house staff members, so that the recommended procedures may be performed safely. Likewise the cardinal principles of care of the infant—the provision of oxygen, heat, and proper feeding—must be translated from the theoretical stage to practical application. All these facts point up the need of additional joint training of physicians and nurses in the care of the premature infant. Because of the number of small premature infants being cared for wholly by practical nurses, a definition of the role that nonprofessional nurses should play in the care of the premature infant is also needed.

One of the important aspects of care which the hospital with the averaged-sized maternity service finds most difficult to provide is the skilled nursing care required by the premature infant on a round-the-clock basis. It has been estimated that if the premature survival statistics of two large hospitals, which have an adequately trained and supervised nursing staff in their premature units, were applied to all premature infants in New York City, the lives of 500 to 600 infants, or 30% would be saved annually. Therefore, the logical step seems to be the provision of special premature centers where such specialized care may be given. Early transfer of premature infants to such centers immediately after birth should be strongly encouraged, particularly for infants weighing less than 4½ lb. (2,000 gm.) at birth. Each hospital should, of course, be expected to provide safe immediate care for the infant prior to transfer, including the provision of heat and oxygen continuously from birth.

It is realized that some of the data of this report are incomplete because of lack of information on the hospital records. The two greatest areas where information is lacking are in the antepartum history of the mother and in the care of the infant in the delivery room. It is in precisely these two areas that concentrated effort may be expected to produce very fruitful results in the solution of the problem of prematurity. While the status of records is primarily an administrative problem within the hospital, complete information must be available to the medical personnel for study as well as for action. The medical directors of the obstetric and newborn services should share in the responsibility for rectifying the situation.

In New York City, approximately 40% of all infant deaths are autopsied annually, in contrast with an 80 to 90% autopsy record in Chicago. It is evident that further interest must be stimulated in this area, if the potential knowledge gained from the study of individual deaths is to be made available for general application. This problem is not only a quantitative one, but the results of the autopsies show that it is also qualitative. There is a great need for more pathologists interested and trained in neonatal pathology. One group in Brooklyn, under the aegis of Dr. Charles A. Gordon, has already taken the first step by providing a pathologist well trained in neonatal pathology. In New York County, plans are being made by the Infant Mortality Committee of the New York County Medical Society for the formation of a team composed of pathologist, obstetrician and pediatrician who would be available to serve as consultants to Manhattan hospitals to perform autopsies on newborn infants and to review the obstetric and pediatric factors in the care of such infants prior to death.

As a result of this pilot study, plans should be made to carry on a continuous investigation of deaths among premature infants in a manner similar to that of the Maternal Mortality Committees. Continuous joint investigations by the Medical Society and Health Department have been successfully carried on for a period of years in Chicago,[13] Philadelphia [14] and Maryland,[15] and have led to the development of joint programs for action.

SUMMARY

This report describes the method used and the findings in a pilot study of 55 premature infants who died in Brooklyn in February, 1949. Certain deficiencies in the recording of information and in the care given to maternity patients and their prematurely born infants are discussed. It is hoped, as a result of this study, that methods will be developed to evaluate and improve such care on a continuing basis.

CHICAGO PLAN FOR CARE OF PREMATURE INFANTS

Julius H. Hess, M.D., Chicago

The importance of proper care for premature infants has been slow in being recognized. While my interest in this phase of the practice of medicine goes back to 1906, it was not until 1922 that a premature infant station of size was finally established in the Sarah Morris Hospital of Michael Reese Hospital in Chicago. This station was willing to accept premature infants from all sources, whether born in a home, at Michael Reese Hospital or at some other hospital where necessary equipment and nursing care were not available. The success in establishing and operating our premature station has been due to the efforts and interests of the Infants' Aid Society of Chicago, a group of philanthropic women now numbering over 1,100 active members, who have supplied most of the equipment for the station, have provided care for a high percentage of our charitable and semicharitable cases, and have established an endowment fund, the income from which may be used only for the employment of nurses in the station or the procurement of breast milk in necessary instances. These activities of the Infants' Aid Society have been given in some detail as a helpful suggestion to other institutions desiring to have a premature station.

In 1922, when our premature infant station was opened, it was obvious that infants born in homes or other hospitals could not be accepted into the clean newborn nursery in Michael Reese Hospital and for this reason the station was located in the Sarah Morris Hospital for Children. The possibilities of the station were slow in being recognized by the medical profession, and the wisdom of opening such a station in a hospital for children was not immediately admitted, as evidenced by the fact that only 19 patients were accepted for care in 1922, 28 in 1923, 47 in 1924, 66 in 1925, and 106 in 1926. From that point on the admissions increased until 492 premature infants were admitted in 1947, 488 in 1948, and 435 in 1949.

By 1932 the demands on the station had reached a point where it could no longer provide for all the applicants who were referred for care, and the small station previously established at Cook County Hospital was enlarged. At the present time the Sarah Morris Hospital station has a maximum bed capacity of 35, and the Cook County Hospital station, a somewhat larger capacity. From 1932 to 1934 these two stations were operated independently but with encouragement from the Chicago Board of Health.

In 1934 the city-wide plan for the care of premature infants was inaugurated, and the Chicago Board of Health and the premature stations at Sarah Morris and Cook County Hospitals combined their facilities for the care of these infants in Chicago and Cook County. The seven basic principles which were established at our station and which are considered necessary to the operation of a qualified premature infant station were included in the Chicago city-wide plan and are discussed briefly.

1. It is obvious that to be of service to the infant the Board of Health must know of its birth. Therefore, in the city of Chicago, all premature births must be reported to the Board of Health by telephone within one hour after delivery, followed by written confirmation within 24 hours. As soon as the report of a premature birth is made, the Board of Health contacts the physician, if one has been in attendance, for his permission to transport the infant to a premature station if such request was not made at the time of reporting the birth. All transportation of these babies, whether from a home to a hospital or from one hospital to another, is done by the Board of Health in a specially designed and equipped ambulance. The nurse who accompanies the ambulance has had special training in the handling of the infant during transportation, especially in emergency treatment. If the baby is in another hospital and is in poor condition, it is suggested that it be kept in an incubator and given oxygen until its condition improves, waiting from 8 to 24 hours before removal to a premature station. If the baby is born at home and is in poor condition, oxygen is administered by the nurse from the Board of Health, and the infant remains in a warm crib supplied by the Board of Health until there is definite improvement in respiration and circulation and is then transported to a premature station. Regardless of where the baby is born, it must be protected against chilling from the time of delivery until transported to a special station. Oxygen is given, at least temporarily, to all premature infants received in our station. Any patient brought to the station from outside is examined only for cyanosis, trauma, and congenital deformities at the time of admission,

limiting exposure to a minimum. Thorough physical examination is delayed until the infant's general condition warrants such procedure.

2. The premature infant stations are supplied with incubators or some type of heated beds, as well as special equipment for oxygen and other emergency therapy.

3. Premature infant stations must have nursing and medical care by trained personnel. It has at all times been our contention that skilled nursing care is the prime essential in reducing premature infant mortality. Best results are obtained if well-trained graduate nurses are in charge. The supervising nurse of the station should be responsible to the pediatrician and should, therefore, be pediatrics-minded. All student nurses taking care of premature babies must receive adequate instruction and must be closely supervised. For the 24-hour period, the nursing personnel should average one nurse for every two to four infants, the number of nurses required depending upon whether graduate or undergraduate nurses are in charge of these babies. In our station there are also nursery maids, who have been trained for one year in the care of newborn and young infants. They spend part of their training period in the obstetric nursery and part in the children's hospital in which the premature station is located. Since they remain in the station for longer periods than the average nurse in training, the personnel is changed less frequently, which is a great advantage, decreasing the amount of personnel instruction necessary.

It is my belief that care of premature infants should be assigned to the pediatric department and that a long period of service in the station should be considered desirable for the pediatrician and resident as compared with the usual short-term rotation service. It has been our experience that an inadequately trained house staff is soon evidenced by increased morbidity and mortality in the station.

4. Breast milk for the infants in our station is supplied or obtained from wet nurses and visiting mothers. The mothers of the babies who are patients in the station express their milk at home and send it to the hospital to be used. The Chicago Board of Health maintains a breast milk station which makes breast milk available without cost to the hospital when it is needed to supplement our own supply.

5. A field nursing service has been developed for instruction of the mothers in the care of infants following their graduation from the station. Special attention is also given to the promotion of breast milk secretion. Breast milk in the home reduces the number of hospital days, and most mothers can be taught hand expression. Psychology plays an important role here.

6. A simple type of heated bed is loaned to graduates for use in the home. This is of great value in reducing the number of cases returned to the hospital due to acute illnesses after graduation from the station.

7. An outpatient clinic is maintained for instruction of mothers and for the care and supervision of graduates. It was recognized early in our station that such a clinic was most desirable because many of our patients come from families in the lower income bracket and frequently do not have private physicians. Many times the private physician in attendance will request that the baby be returned to the clinic during the early months after graduation. It is important that the follow-up clinic have as its objective good physical growth and mental development in the child, factors which are as important as a low mortality and morbidity rate. The increasing importance of our outpatient clinic is shown in the following statistics:

	1946	1947	1948	1949
New cases	111	101	135	145
Individuals in year.....	339	408	376	450
Visits	1,315	1,576	1,827	2,644
Visits per individual....	3.66	3.86	4.86	5.87

Illinois, through its Department of Public Health in Springfield, has a well-defined program for the care of premature infants. Three stations are now in operation outside Cook County, and plans for six more are being completed. Through the use of premature centers that meet the standards of location, space, physical equipment, and specialized medical and nursing care, the Illinois Department of Public Health provides hospital and nursing care not available in all localities for the premature infants of all economic levels, gives economic assistance to families who lack the necessary funds for specialized medical service in caring for their premature infants, and thus provides a means to aid in diminishing mortality attributable to prematurity. Through grants of funds from the Children's Bureau the centers have been paid for hospitalization of infants who would otherwise be denied this special care. Similar financial arrangements have enabled the Department of Public Health to pay, where necessary, for the ambulance transportation of infants from outlying areas of the state to the centers. Funds have also been made available for providing special training for nurses serving in these centers. Integration of the phase of hospital care with later home care has been accomplished through the cooperation of local health departments and public health nurses.

To meet the needs of and the increasing demands for trained personnel, voluntary training centers must be established throughout the United States. Michael Reese Hospital has encouraged a program of special training for physicians in the care of the premature infant, and many physicians, supervisors of state and city boards of health, and supervisors of individual hospitals have taken advantage of an opportunity for observation in our station. A six-weeks' course for nurses is given at the Sarah Morris Hospital premature station, covering not only the theoretical but also the practical application of care of the premature baby, the latter including experience in the station, in the outpatient department, and on home visitation. Various training programs for nurses are being offered in other qualified centers, such as the Harriet Lane Home of the Johns Hopkins Hospital in Baltimore; Columbia-Presbyterian Medical Center and New York Hospital-Cornell Medical Center in New York; Cook County Hospital premature station, Chicago; Los Angeles General Hospital; Colorado General Hospital, Denver; Oklahoma University Hospital, Oklahoma City; Charity Hospital, New Orleans, and the Margaret Hague Hospital in Jersey City. It is unfortunate that there are so few training centers in this country and that these are so limited in the number of nurses that can be trained. It is my belief that nurses must be offered this type of training at the expense either of the state or the individual hospital to which they will return at the completion of the training period.

Having become interested in state-wide programs for the care of premature infants as they are carried out in this country, in 1949 I wrote to the Divisions of Maternal and Child Health in all of the states as well as Alaska and Hawaii in an effort to determine what progress had been made in those localities. The replies received from 44 states and the two territories indicated as many variations in the program as there are Divisions of Maternal and Child Health. Although no state has established a fully satisfactory state-wide program, nevertheless, much progress has been made.

NATION-WIDE PLAN FOR REDUCTION OF PREMATURE MORTALITY

Leona Baumgartner, M.D., Washington, D. C.

The federal grants-in-aid system for health purposes is based on the principle that problems and resources vary widely and that each state moves at its own speed. An excellent study recently reported indicates that Kings County was ready to move forward in an important way in tackling the problems of saving the lives of premature babies before any of the other counties in the Greater New York area. So I interpret "a nation-wide plan" to mean a statement of general principles, the application of which will vary widely from one state or community to another.

Infant mortality since 1915 has been reduced two-thirds, from 100 deaths per 1,000 live births in 1915 to 31 deaths in 1949. Improved sanitary conditions (such as the elimination of the house fly and pasteurization of milk), improved living standards, better nutrition, and improved medical practice have played a part in this reduction.

Certain specific steps can be identified in the downward progress of infant mortality. First came the realization that the extent of the problem was not known. For example, when the federal Children's Bureau was organized in 1912, no one knew how many infants were born or how many died in the first year of life. A campaign for birth and death registration followed. Then came studies by physicians to determine why these babies died and which deaths were preventable. Out of the knowledge gained through these two approaches to the problem, practical steps were taken. Doctors and nurses received additional training, emphasizing what they must do not only to care for the sick but also to prevent the conditions which lead to death; the public was told what it needed to do; public health departments and hospitals and other community groups organized special services to tackle the problem.

As time went on, practice was changed to take into account what scientific research was developing, such as better methods for pasteurization of milk, newer knowledge of nutrition and food production, and more effective health education.

The problem of prematurity presents the same sort of challenge that infant mortality did 35 years ago, and I believe that the same kinds of activities must be undertaken if we are to be as successful in reducing the deaths associated with premature birth. First, we need to know the extent of the problem. New York city, for example, knows its incidence of premature birth and knows its mortality rates, because for some 10 years birth weight has been included on birth certificates filed in the city. But for much of the rest of the United States this is not true. Even the definition of a prematurely born infant has varied from hospital to hospital and from area to area. Nineteen-fifty marks the first year in which birth weight, the most generally agreed single criterion of prematurity, will appear on birth certificates in all of the states.

States and communities need to be encouraged to analyze the facts in their own localities. Recording birth weight on all birth certificates will tell how many prematures there are and how many survive.

Another step is to analyze deaths occurring in a local area with a view to finding out "why." This is the sort of pioneering job that was done in Kings County. The County Medical Society worked hand in hand with the local health department to uncover the facts. Nurses and doctors worked together to find the weakness, the gaps in service that made the difference between life and death. They have results which point to the corrective and productive measures to be taken. Such studies are a first and important step in any national drive to reduce deaths associated with prematurity. They focus the attention of the profession on the problem. High-lighting of what needs to be done next has been essential in every lifesaving effort made in this country, and it is important that physicians and nurses do this part of the job themselves.

Although not all states have complete figures, there is considerable knowledge of the extent of the national problem. From what doctors record on death certificates as the primary cause of death, we know that premature birth is the leading cause of infant death today, and that the numbers of such deaths are sufficiently large to make prematurity the eighth cause of death among persons of all ages. How many persons are concerned that in 1947 physicians declared that prematurity was the chief cause of death for 41,000 citizens of the United States? An epidemic of disease that involved that number of persons would call forth the concerted action of all the nation's doctors and nurses, of national, state and local governments, and of citizens' groups everywhere. Why should we do less because the cause of death is premature birth? Physicians know that not all these deaths can be prevented with the scientific knowledge at hand and realize

Presented before the Kings County Medical Society and the Academy of Medicine of Brooklyn, April 17, 1950.

that probably there will always be an irreducible minimum representing certain genetic and developmental failures that cannot be saved. The time has come for a nation-wide effort to see that every mother gets the kind of care during her pregnancy that improves her chances for being delivered of a full-term infant, and that every prematurely born infant gets a chance at those measures which have proven effective in saving life.

Let us see what factors influence survival and what can be done about them. The first generally recognized and scientifically verified fact is that the smaller the baby the less his chance for survival. Figures for New York city for all babies born prematurely in 1947 (not just those cared for in certain hospitals which give an incomplete picture) showed, for example, that the mortality rate in babies weighing less than 2,500 gm. (5½ lb.) was 13 times that of babies weighing more than 2,500 gm.

Mortality rates reported for different groups weighing less than 2,500 gm. vary widely. To make any valid comparisons, it is necessary to know the composition of the group. Obviously if a larger proportion of small babies are included, rates will be higher. This has long been recognized, but the recent analyses of Taylor, Eastman and others indicate that other factors are at work. In the two-year-old Colorado program (one of the most comprehensive programs undertaken in this country), Dr. Taylor found that in every weight group there is a significantly greater mortality for infants born from abnormal pregnancies or deliveries, the difference in a group of 477 infants being 8% for the "normals" and 37% for the "abnormals." In Eastman's study premature birth occurred in 24.9% of his patients who had poor prenatal care or none, as compared with 7.8% of those who had good care.

This again points to the importance of the obstetrical factor in this problem of reducing deaths associated with prematurity. Actually herein lies, perhaps, our greatest job and one that is all too often overlooked by those who advocate so-called premature programs. It is the general practitioner who attends most women during pregnancy and delivery. The first job is to put into his hands the tools necessary to enable as many women as possible to carry their fetuses safely to term and through delivery.

We must not forget, either, the several important studies that have conclusively shown that the woman who eats an inadequate diet during her pregnancy is more likely to have a premature infant. Although too few doctors take cognizance of this fact as they provide care for women during pregnancy, all doctors have recognized that the social and economic conditions under which the pregnant woman lives influence the outcome of her pregnancy as directly as the type and amount of medical care she receives.

The second part of the job is to bring to the care of those prematurely born the best that modern pediatrics has been able to evolve. The guiding principle is simple enough—to give the infant the help he needs to meet the hazards of life as well as or better than his full-term sibling. So come the much publicized incubators, ambulances, oxygen, transfusions, and specialized premature centers. These are the devices that have so far proved of value in saving lives. But one of the questions we have not answered is how to organize services to bring the best care to all babies? How much can the general practitioner and the small hospital carry by themselves? What training do they need to carry the load? When should they have and how best can they secure the additional expert help they need? What is the best use to be made of the "premature center"? The trend seems to be toward having every nursery and every doctor equipped to care for the larger and healthier premature and to develop some kind of regionalized service to bring consultation and expert care to those cases whose needs cannot be met by the general practitioner or the small hospital. The Children's Bureau in cooperation with some state health departments and the Academy of Pediatrics is now planning studies that may give some answers to this problem of getting the most effective care to all prematures.

These are some of the important trends and facts of the problem of prematurity from the medical point of view. One additional fact often overlooked is that the public has an enormous interest in the subject.

What are various parts of the country doing about the problem of premature babies? Although different states are attacking this problem in different ways, a basic pattern is beginning to emerge. Most activities are guided in part by state and local health departments, and are financed in part by the federal grants-in-aid programs provided for under the maternal and child health provisions of the Social Security Act. The following activities are usually included: 1. Training of nurses and physicians in the care of premature infants. This is a widespread activity. 2. Development of hospital standards and licensing, emphasizing facilities and personnel for proper care of premature infants. 3. Consultation to hospitals (principally by nursing consultants so far) in an effort to raise the standards of care for full-term as well as premature infants. 4. Loan of incubators, together with consultation regarding their use. 5. Transportation of premature infants to premature infant centers. 6. Development of premature infant centers and purchase of hospital care for them. 7. Measures designed to prevent premature labor, such as: more and better prenatal services, with emphasis on diagnosis and the importance of adequate nutrition; obstetric consultation for complications during pregnancy; hospitalization for complicated pregnancy; and obstetric consultation aimed toward improving the management of the mother's labor and delivery in cases of premature birth (since most of the premature infant deaths occur on the first day of life).

Most state health departments are carrying one or more such activities. Some have programs which include virtually all of them. Many have made equipment, especially incubators, available to hospitals. Many have been more interested in saving the lives of those prematurely born than in the fundamental task of improving the quality of obstetric care in order to delay such births until a safer period. Some states have done a remarkable job in the latter area. In Virginia, for example, any physician faced with a complication of pregnancy can have an obstetrician help carry the patient through delivery, and the state health department pays the bill. Such programs are being planned for other states as soon as funds become available.

Within the last few years, "centers" have been set up in Colorado, Hawaii, Illinois, Louisiana, Maryland, New York, North Carolina, Tennessee, and West Virginia, and other states have plans for centers as soon as funds become available. What constitutes a center for premature babies? Space is usually allotted in the hospital separate from the nursery for the full-term babies. The set-up does not have to be elaborate; many are very simple. All centers for premature babies concentrate on (1) providing skilled medical and nursing care with the least possible amount of handling; (2) maintaining the baby's normal body temperature, therefore the incubator; (3) safeguarding the baby against infection; and (4) adequate feeding.

Many centers concentrate on care for the smallest babies. Provision is usually made for the safe transport of the baby to and from the center. And the better programs also concentrate on improving the obstetrical care of the mother during pregnancy and delivery. It has been quite commonly observed that these measures lead to better care for all babies.

Often the care needed by the premature baby is long-time, expensive care that is beyond the ability of the average family to pay. In the West Virginia program, for example, the average cost of care for 145 infants was $341.70 per infant. In the North Carolina program the average cost of care for 441 infants was $411.48. These figures, however, do not show the wide range in costs for care of infants in different weight groups. Neither do they give an adequate picture of the expenses faced by a family having a premature infant.

The smaller the baby, the greater is the cost of care. For example, in Colorado, among 29 babies in the weight group 1,000 to 1,499 gm., the average cost of care was $827 per infant, but for 25 per cent of the infants in the group the cost exceeded $1,000. For 53 babies in the weight group 1,500 to 1,999 gm., the average cost was $572. For 81 infants weighing 2,000 to 2,499 gm., the average cost per infant was $199.

About 50 per cent of the Colorado infants required hospitalization costing $400 or more each. The social data on the first 175 patients in the Colorado program showed, and a committee of the state medical society agreed, that 174 of these families could not pay the costs of care.

The states are paying the hospitals, for the most part, the average reimbursable cost. This is high. In West Virginia, for example, the state agency pays the hospital $18.45 a day for the care of the premature infant. In Colorado the per diem cost is about $25.00; the state agency pays half of this, and the other half is paid through state appropriations to the hospital.

What has been done in the United States so far in a national program for premature infants is that a few hesitant steps in the right direction have been taken in many states. There is evidence of a great interest on the part of doctors, nurses and the public in moving ahead more rapidly. The studies of the state academies of pediatrics are providing a strong stimulus to the development of services for premature infants. Many of them are recommending that health departments emphasize such services. Thirty-three state health departments reported recently to the Children's bureau that they would develop or expand programs for premature infants in their states, if additional funds became available.

The development of services for the care of premature infants on a nationwide basis will be speeded up by the establishment of several well-developed training programs. The problem of training is complicated by the fact that different personnel need different kinds of training. For example, a number of articles have recently appeared dealing with the fact that what happens to a premature infant during delivery directly affects his chance of survival. The choice of the anesthesia and the type of delivery may be extremely important. As the Kings County study has so ably shown, we can no longer assume that two 1,500 gm. prematures are alike because they weigh the same. They may be vastly different in their potential for living because of the experience they have just gone through. Training in anesthesia and obstetrics for the general practitioner is a part of a so-called premature program that is often over-looked. The general practitioner is eagerly looking for ways of keeping up on the latest advances and welcomes short, intensive periods of training, or refresher courses on obstetrics, which would include the immediate and emergency care of infants under 2,500 gm.

The premature program is truly a medical care program in high gear. The care of the premature infant is always an emergency. The timing of the services and their coordination spells survival or death to the baby. Emergency care at birth, transportation, care in the hospital, careful planning on discharge, continuing care in the home and follow-up must all merge into a smooth-flowing service to meet the needs of the individual baby and his family.

This can be achieved only if there is continuous planning by all the people working in the program. Experience has shown that one of the ways to accomplish such planning is for the people who are concerned to get together regularly to discuss, criticize, and revamp the services in light of their experiences. What are the difficulties encountered? Where does the program bog down? Are there personnel who need further training? Do health officials and physicians understand and use the service? Do other workers in closely related services use it? Do the parents know about and seek the services? All of these questions must be answered if premature infants are to receive the care they need to survive.

The emergency character of the program puts a premium on well-coordinated planning, both in and out of the hospital, for actual care, and in the community for supplementary services and support. State and local health agencies must co-operate with medical, nursing, and welfare agencies if services are to be complete and well-rounded. A public health nurse may be needed to go into the home when a premature infant is being discharged to it. The help of a child welfare worker may be needed to find a foster home, or to help parents meet their problems, or to help the unmarried mother plan for her child. "Aid to dependent children" may need to be used as a financial resource for helping the child.

State and local advisory committees including citizens and members of the various professions and agencies, both public and voluntary, are needed to help plan the program and arouse public interest in it. Only as the people and the community appreciate what the problem of caring for these babies means can they give the program their support.

It is with great pride, of course, that I point out that today in New York city everything that is needed to tackle this problem of prematurity is available. The program is not yet in high gear and has not yet realized its fine potentialities in lifesaving, though I would hazard the guess that the recent sharper reduction in infant mortality recorded here is in no small measure associated with the excellent program that has taken shape in these postwar years. Facts and figures now become available from the health department. Some facilities for training doctors and nurses in modern obstetric and pediatric care are now available, though probably many of those who need it most do not avail themselves of the opportunities. Almost all births occur in hospitals, and an increasing number of these hospitals are equipped and staffed to give the kind of care that will help carry the pregnant woman to term and to care for the baby properly if it is born prematurely. A few excellent premature centers, concentrating their attention on the babies most in need of care, have been established. Excellent transportation facilities are provided. Plans have been made to help pay for care for those who cannot afford to pay for it themselves. The Children's Bureau has realized that providing funds to pay for hospital care is essential to a really effective program and congratulate New York city in leading the country in these plans. The city has also continued studies, active studies by the doctors themselves, of all deaths of mothers and, recently, of prematures. In such activities Brooklyn has done and is doing more than the other boroughs. The projected study of the Academy of Medicine should prove another milestone for the city at large. Basic research in the causes of premature labor and in better ways of caring for premature infants is going on in the educational institutions there. The public is interested and willing to support further endeavors. These are the elements of a good program as seen today. To be sure, not all women, even in New York city, get good prenatal care now, or the best of care during delivery, or the food they need during pregnancy. Many infants still die today in hospitals of that city because they do not get the care they should. A modern and effective licensing system for hospitals (comparable to those in operation elsewhere) still needs support. More attention needs to be paid to the obstetrical aspects and to prevention. Better educational programs for parents and professional groups need to be developed. In other words, New York city has a superb opportunity to lead the entire nation in a program of saving infant lives just as it has led in developing many other public health programs.

However, leadership cannot be maintained without continued and constant attention to planning the many details that such a complicated program requires. There must be constant vigilance if no essential part is to be allowed to lag in actual operation.

To return to the national picture, we in the Children's Bureau have reviewed the situation very carefully in the past six months. We believe the time has come to make a concerted drive to save the lives that are being lost today in the United States because of premature birth. Each community will and should tackle the job in the way best suited to its own needs and in accord with its available facilities and manpower. But every community should move as rapidly as it can toward a comprehensive program of service. Such a program should strive toward eight goals.

1. It should use first-rate facilities, staffed with well-trained personnel.
2. It should provide consultation services to hospitals and doctors.
3. It should include measures designed to prevent premature labor.
4. It should provide transportation for, and pay for hospitalization of, premature infants when necessary.
5. It should take cognizance of the important role of the general practitioner and bring to him the help he needs to carry on.
6. It should plan with the family for adequate care for the premature after discharge from the hospital.
7. It should plan for continuing evaluation of activities and results as well as continuing education of the public to use the services available.
8. It should provide for team work in planning and operating the program.

Not all community programs can engage in research. A national program would be incomplete if it did not envisage greatly expanded basic research activities designed to discover more effective ways of preventing prematurity and thus contribute to reducing this problem to easily manageable proportions.

In every community one step which can be taken immediately is a co-operative study by a county or state medical society and the local or state department of health to discover the facts concerning the causes for and the possibilities of preventing deaths associated with premature birth. This might well be the opening of another large campaign to save infant lives in this country.

Chemical Carcinogenesis.—Until recently, our picture of the carcinogenic process envisaged damage of the normal growth mechanism as the primary effect. At present (at least so far as the mustards are concerned, we now picture damage to the chromosome by direct combination with genetic material, followed maybe by the generation of a new and self-duplicating chemical and genetic rearrangement. . . . Compounds . . . have been shown . . . to have a varying degree of preferential action at certain specific chromosome regions, especially the so-called heterochromatic regions known to have characteristic chemical and genetic properties, the latter associated not so much with Mendelian inheritance as with the quantitative inheritance of growth-rate and differentiation features and their mutation. . . . There would appear to be—and for the first time—some prospect (if only a prospect) of correlating the chemical properties of a given carcinogen with the chemical properties of specific chromosome regions, with the resultant cytological effects, and with the genetic consequences to the cell which thus ensue.—A. Haddow, M.D., Advances in the Study of Chemical Carcinogenesis, Proceedings of the Royal Society of Medicine, April, 1951.

BIRTH WEIGHT AND LENGTH OF GESTATION WITH RELATION TO PREMATURITY

Matthew Taback, A.M., Baltimore

Newborn babies and infants under 1 year of age have been among those to benefit most from advances in medical science and the efforts of public health agencies during the first half of this century. Reviewing the Baltimore City vital statistics reports at the beginning of the century, one finds that the infant mortality rate was approximately 200 infant deaths per 1,000 live births. Simply stated, this means that in 1900 of every 100 babies delivered alive 20 failed to reach their first birthday. The loss of human life and wasted pregnancy occasioned by the existence of such a high infant mortality rate are difficult to comprehend. Principal causes of infant deaths in 1900 were diarrhea, pneumonia, acute communicable diseases, prematurity and congenital malformations. A review of present day records indicates that the infant mortality rate has decreased at an unbelievable rate and stands now at about 30 infant deaths per 1,000 live births, an 85 per cent decline since 1900. Principal causes of infant deaths today are prematurity, congenital malformations and birth injury.

With a firm belief that further savings of human life can be achieved, the Children's Bureau has requested local registration offices to include inquiries on the birth certificate to provide data that will assist in the study of factors associated with prematurity, congenital malformations and complications of pregnancy. Therefore, starting Jan. 1, 1949, the birth records in Baltimore City have included a medical data section, which is completed by the attending physician. This section consists of the following items: length of pregnancy, birth weight, complications of pregnancy and labor, operations for delivery and a description of birth injuries or congenital malformations when present.

In view of the completeness of the data submitted by attending physicians, it was decided to analyze the material available on birth weight and length of gestation in order to study some of the relations between maternal factors and the prevalence of prematurity and to look into the relation that exists between length of gestation and birth weight.

NATURE OF DATA

The birth records for resident babies born during the period January to June 1949, described below as sample A, were used in the current study. Statements concerning birth weight are received either in pounds and ounces or in grams. All statements are coded into 500 Gm., categories. Length of gestation is reported in weeks, and the information is used in this form. Occasionally, reports are received in terms of months; these statements are then revised so that, in the coding process, the total period of gestation is reported in terms of weeks instead of months.

A total of 9,709 babies were born during the study period. The birth records of 9,523 contained statements concerning birth weight, and, of these, 9,392 also had data concerning length of gestation. Thus, 97 per cent of all birth records processed had completed statements in respect to length of gestation and birth weight.

Owing to bias found on the analysis of statements concerning length of gestation, a sample of clinical records was studied. These records were drawn from three subsamples:

Sample	Description	Number of Cases	Race
B	Outpatient service of a teaching hospital....	419	White
C	Private service of an obstetrician............	243	White
D	Antepartum service of the Health Department	200	Negro

Only cases active during the period 1947-1949 and meeting the two criteria which follow were considered: first day of last menstrual period specified and pregnancy terminating in delivery of a single liveborn baby.

DEFINITIONS

Prematurity, when used in this study, follows the definition recommended by the American Academy of Pediatrics.[1] "A premature infant is one who weighs 2,500 grams or less at birth regardless of period of gestation." Because of the manner in which data were processed, prematurity in this analysis refers to babies with birth weight less than 2,500 Gm.

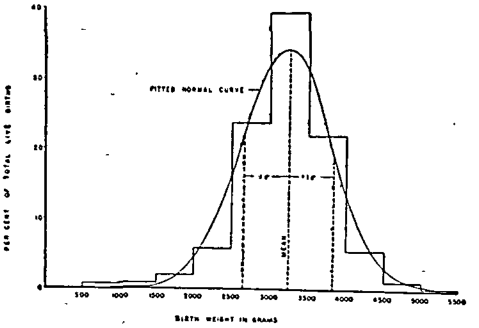

Chart 1.—Resident live births by birth weight, all races, Baltimore City, January-June 1949.

It must be recognized that, although the definition proposed by the Academy has simplicity and objectivity, it is highly problematical whether such a definition can carry with it much validity when one considers the wide somatic variation that humans can take without any effect on their physiological responses. The deficiency in this definition will be further discussed below.

Length of gestation refers to the interval that intervenes between the first day of the last menstrual period (considered the beginning of gestation) and the date of birth. This definition is the one most commonly applied in the literature available on this subject.[2]

Director, Bureau of Biostatistics, Baltimore City Health Department.

Presented before the Public Health Conference on Records and Statistics, Washington, D. C., April 24, 1950.

Dr. W. Thurber Fales, Director, Statistical Section, Baltimore City Health Department assisted in the design of this study.

This paper is one of a series of quarterly studies prepared by the Bureau of Biostatistics dealing with quantitative aspects of current medical problems.

FINDINGS

Birth Weight.—The birth weight distribution for babies born during the first half of 1949 (sample A) is given in table 1 and shown in chart 1. Distributions are also given for race segments and for single and plural births.

Examination of chart 1 indicates that newborn babies show wide variation in weight at birth. The distribution approaches symmetry and is centered at 3,204 Gm., the mean birth weight, with a standard deviation of 579 Gm. The curve shows greater concentration at the center than a normal distribution and is skewed in the lower birth weights. Mean birth weights for white and for Negro liveborn babies are 3,244 and 3,116 respectively, the difference being statistically significant.

* The prematurity ratio is the percentage relation of premature births to total births.

When the prevalence of premature babies (under 2,500 Gm.) is considered, one finds that 8.9 per cent of all babies fall in this category. Negro babies, when weight alone is considered, apparently have a prematurity ratio of 12.0 as compared with 7.4 for white babies. Whether this is indicative of a greater prevalence of prematurity among Negro babies has been questioned by recent investigators. Peckham,[3] in a statistical study of prematurity, describes the neonatal mortality experience for liveborn infants by birth weight and race. White babies, weighing 2,500 Gm. at birth, were subject to a 4.7 per cent neonatal mortality rate. Negro babies at this weight had a more favorable experience, the neonatal rate approximating 2.2 per cent and reaching 4.7 per cent at about 2,320 Gm. Accepting the neonatal rate as a criterion of physiological performance, Negro babies of 2,320 Gm. are equivalent to white babies of 2,500 Gm. weight. When the prevalence of Negro liveborn infants with birth weights less than 2,350 is determined, it is found that the index of prematurity shown in table 1 as 12.0 per cent is reduced to 7.2 per cent.

In table 2, prematurity ratios as well as total number of births are distributed by age of mother and birth order. The interpretation of these data can be best understood by referring also to chart 2.

Confining our analysis to data describing the prematurity experience for all races combined, we find that the mean prematurity ratios for successive birth orders show no significant difference. When the effect of maternal age is considered, there is an indication of a higher mean prematurity ratio for mothers below 20 years old than there is for older groups. These observations do not reflect the chief sources of variation in prevalence of prematurity among newborn babies. When birth orders are considered separately or in groups in relation to age, two significant trends are noted: There is an optimal age for first order births (22.5 years), and risks of prematurity rise gradually for both younger and older mothers; for later order births, high risks of prematurity are associated with young age groups with a minimum at age 27.5 followed by a comparative plateau at the minimum level.

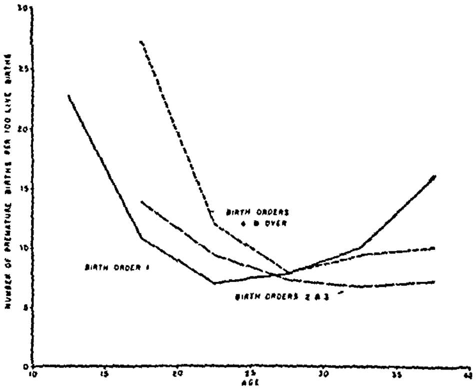

Chart 2.—Premature ratios for live births by age and birth order, Baltimore City, January-June 1949. The solid line indicates birth order 1; the broken line, birth orders 2 and 3, and the dotted line, birth orders 4 and higher.

In a study of the maternal age distributions, it was noted that 26 per cent of the Negro mothers were below the age of 20, compared with 10 per cent of the white mothers. The effect of the differential of age distributions on the prematurity ratio was studied by standardizing the Negro distribution according to the white maternal age distribution. This procedure reduced the nonwhite prematurity ratio to 11.0 per 100 live births, an 8 per cent reduction from the index of 12.0 shown in table 2.

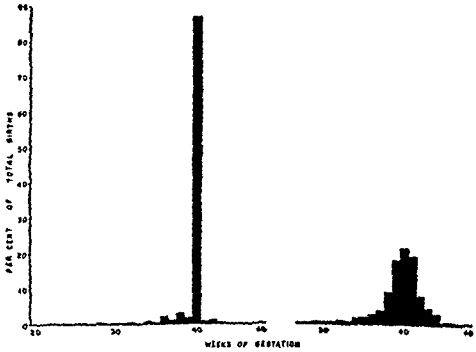

Chart 3.—Frequency distribution of single live births by length of gestation. The distribution for sample A (Baltimore City, January-June 1949) is shown at the left; that obtained from the summary of clinical records (samples B, C and D), at the right.

Length of Gestation.—In table 3, the distribution of single births according to length of gestation as obtained from birth records (sample A) is compared with a distribution obtained from a composite of clinical records (samples B, C and D). These distributions are graphically presented in chart 3.

As indicated in a discussion on the nature of data used, extreme bias is indicated in sample A. Higher frequencies are associated with even weeks throughout the distribution. There is a peculiar concentration of values in the 40 week class, 87.2 per cent of all births being reported in this category. These data were considered to be grossly in error in view of the usual manner in which all organisms tend to vary about a center value in respect to biological variables. In order to test the validity of the data submitted on birth records relative to length of gestation, a study of clinical records was undertaken and some of the resulting data are shown in table 3 and chart 3. It is interesting to note that the distribution obtained shows no bias in respect to selection of even weeks for higher frequencies, nor is there to be found a sudden rise in frequency at 40 weeks' gestation. The distribution obtained by study of clinical records is negatively skewed and gives evidence of leptokurtosis ($B_2 = 6$).

Studies of other investigators working directly from patient histories have resulted in distributions of single births by length of gestation similar to the composite distribution shown in chart 3.

Karn [4] presents data based upon 3,275 births of white infants and obtains a curve similar to that found in the study of clinical records with a mean of 278 days and a standard deviation of 16.3 days, or 2.33 weeks. Anderson, Brown and Lyon,[2] in a study of 4,843 births, obtained distributions for white and Negro infants with means of 279.5 and 274.0 days, respectively, and a standard deviation of 21 days, or 3.0 weeks.

On comparison of samples B, C and D, it appears that Negro mothers have a mean duration of gestation somewhat shorter than white mothers. Likewise, the percentage of births of 37 weeks' gestation or less among Negro mothers is twice that observed among white mothers of comparable socioeconomic status (sample C).

Compared with the composite of clinical records, the health department records grossly understate the frequency of occurrence of births of durations other than 40 weeks. This phenomenon results principally from a working rule in hospitals that newborn babies with birth weight of 2,500 Gm. or more are regarded as full term and gestation is given as 40 weeks without reference to the patient's history.

Length of Gestation and Birth Weight.—In view of the marked bias relative to statements of length of gestation found on birth records, it was considered unwise to employ this material in a study of the interrelationships between birth weight and length of gestation. Such material as was obtained from birth records is given in tables 4 and 5.

A distribution of 656 white single births (samples B and C) by birth weight according to length of gestation is given in table 6. An examination of mean birth weights for specified gestational periods gives indication of a catalytic or growth curve reaching an asymptote of approximately 3,450 Gm. The nature of the curve is quite similar to the regression of birth weight on length of gestation reported by Hosemann [5] in a study of 12,000 cases, although the latter investigator gives birth weight values for early gestation ages somewhat lower than observed in this analysis.

TABLE 7.—*Percentage Distribution of Single White Live Births According to Alternative Definitions of Prematurity*

	Birth Weight		
Length of Gestation	Below 2,500 Gm.	2,500 Gm. and Over	Total
Over 37 weeks..............	3.3	86.3	89.6
37 weeks and below........	3.0	7.4	10.4
Total..................	6.3	93.7	100.0

The wide variation of birth weight within given gestational periods is not unexpected ($\sigma = 500$ Gm.). When births are distributed according to the two commonly accepted definitions of prematurity—i. e., length of gestation equivalent to or less than 37 weeks [6] and a birth weight less than 2,500 Gm.—the distribution shown in table 7 results.

Of the babies judged premature by weight alone, about 51 per cent appear to be mature babies in terms of duration of gestation. When classified according to both criteria of prematurity, only 3.0 per cent of all live births appear to meet these definitions of prematurity. It is obvious, therefore, that mortality studies of premature infants when classified by birth weight alone may understate the risk involved in view of the inclusion in the exposed-to-risk group of a segment which is probably mature but small in stature.

SUMMARY

Recognizing the need for data on the prevalence and causes of prematurity, the Bureau of Biostatistics of the Baltimore City Health Department has analyzed statements submitted by attending physicians relative to birth weight and length of gestation of infants born during the period January to June, 1949. These data have been supplemented by special studies made directly from clinical histories.

Accepting a birth weight of less than 2,500 Gm. as the sole criterion for classification, 7.4 per cent of white babies and 12.0 per cent of Negro babies are prematurely born. In view of the more favorable neonatal mortality experience among Negro babies of low birth weight as compared with white babies of equivalent weight, it has been suggested that 2,350 Gm. would be a more logical limit for classifying nonwhite babies in respect to prematurity. When this limit is employed, the differential in percentage prematurity between races is eliminated.

Statements concerning length of gestation as found on birth records have shown marked bias. It appears that this stems from the working principle followed in hospitals of presuming that all infants of 2,500 Gm. birth weight or over are full term (40 week) babies. Careful study of clinical histories indicates that approximately 7.4 per cent of white babies are mature in respect to birth weight but are below 38 weeks' gestation and, conversely, 3.3 per cent of live born babies may be mature in duration of gestation and, nevertheless, below the established birth weight level for maturity. Only 3 per cent of white babies appear to meet the definitions of prematurity both in birth weight and duration of pregnancy.

In evaluating programs concerned with the care of premature babies and the prevention of prematurity, we must utilize criteria in addition to birth weight to avoid inclusion of infants who represent mature small babies in premature study groups. Persistence in the use of a rigid definition of prematurity in terms of birth weight for all racial and national groups will mask the differential mortality analysis of infants who are below the birth weight standard of 2,500 Gm., but who are mature as determined from the other criteria, such as length of gestation and neonatal mortality experience.

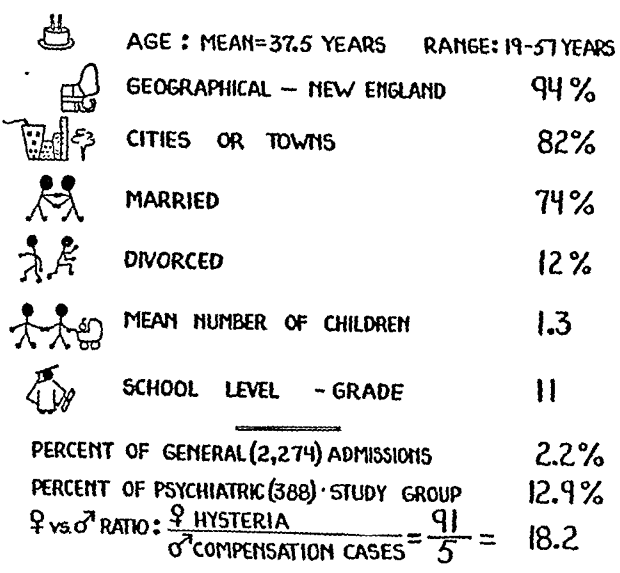
Contact Dermatitis.—Two important causes of contact dermatitis have been re-emphasized during the past year. One of these contactants is cocobolo wood, which is important because it is used in the manufacture of the handles of steak knives and forks, pocketknives and butcher knives, musical and scientific instruments, handles of pressure cookers, chessmen, rosary beads, etc. In most cases, the dermatitis is on the hands as would be expected. The other contactant is the cosmetic rubber sponge used by many women as an applicator for cosmetic powders, "pancake" make-up preparations, etc. It is well known that rubber products are important causes of contact dermatitis, but this sponge rubber is a special preparation and apparently has been used extensively in recent years. Most of these patients have dermatitis of the face and the neck.—C. S. Livingood, M.D., Dermatology, in Medicine of the Year, Philadelphia, J. B. Lippincott Company, 1951, page 54.

OBSERVATIONS ON CLINICAL ASPECTS OF HYSTERIA

A QUANTITATIVE STUDY OF 50 HYSTERIA PATIENTS AND 156 CONTROL SUBJECTS

James J. Purtell, M.D., Milwaukee †, Eli Robins, M.D., St. Louis
and
Mandel E. Cohen, M.D., Boston

Hysteria (*ὑστέρα*) has been noted by physicians since antiquity,[1] but no consistent clinical picture to accompany this term has clearly emerged from the medical literature. The study reported here was undertaken for the further investigation of clinical observations that suggested that hysteria as seen in hospitals in New England presents a rather definite clinical picture. The study was undertaken for the determination, first, whether the clinical impression of the relatively constant pattern of hysteria was a true impression; secondly, to provide factual data that might be useful to the clinician in the diagnosis of hysteria, and thirdly, to provide a sound clinical basis for further research in hysteria.



The group characteristics of 50 women with hysteria.

SELECTION OF PATIENTS WITH HYSTERIA

The patients selected for this study were 50 women with hysteria examined in a diagnostic hospital in New England. All patients admitted to the hospital were referred by their own physicians as presenting diagnostic problems for consultation and further investigation.

During the six month period covered by this study 2,274 patients were admitted to the hospital. Approximately one third of these (671) were referred by the medical services for psychiatric evaluation. Three hundred and eighty-eight of this group, of which 267 were women and 121 men, were examined by at least one of us (M. E. C., J. J. P.). The diagnosis of hysteria, simple or complicated by other disease, was made for 91 of the 267 women patients of the special research group. For none of the men was such a diagnosis made, although during the period of this study the diagnosis of "compensation neurosis" was made for five men. Of the 91 women with hysteria, 50 were included in this study. Of the 41 patients not included, 15 had proved or strongly suspected medical or psychiatric disease in addition to hysteria; eight had only a questionable diagnosis of hysteria, and eight were examined by only one of the examiners. Ten other patients with hysteria were examined clinically, but observations for this study were not made on them. General features of the 50 women with hysteria in this study are summarized in the figure.

METHOD OF STUDY

All patients studied by the psychiatrists were admitted to the medical services, where a thorough medical diagnostic study, including laboratory work-up, was done. This included, in addition to a complete physical examination, a chest x-ray, urinalysis, sedimentation rate determination, serology and the usual hematological studies in all cases. Stool examinations, basal metabolic tests, electrocardiograms and skeletal x-rays were done in more than half the cases. Gastrointestinal x-ray studies were made in 48 per cent, and other special studies, such as spinal fluid examinations, electroencephalograms and proctoscopic examinations, were done as indicated. Tests for urine porphyrin were done in 98 per cent of the cases, and the reactions were negative. Patients included in this series showed no important or diagnostic abnormalities. This was used as additional evidence that the diagnostic criteria excluded any other medical illness, since the laboratory data were reviewed after the patient was admitted to the series. The patients were studied by the psychiatric service when the medical services suspected the presence of some type of psychiatric disease. In the 50 cases reported, the diagnosis of hysteria was made by two of us (M. E. C. and J. J. P.) when there were many features characteristic of the disease and when no other diagnoses, medical, neurological or psychiatric, were present or would explain symptoms at the time of the examination. A follow-up study was done by means of letters sent to the patients and their referring physicians four or more months later to ascertain if any other obvious disease had developed. Information was received on 84 per cent of the patients, and since no medical disease had developed in any one of them in this period of time, this was thought to be a further indication that the diagnostic criteria used excluded medical illness.

---

† Dr. Purtell died on June 10, 1949.

From the Department of Psychiatry of the Tufts College Medical School (Graduate Division) and the Departments of Medicine and Obstetrics of the Harvard Medical School.

Patients and control subjects were selected from and examined in the psychiatric and medical services of Joseph H. Pratt Diagnostic Hospital, in the clinic and Psychologic Laboratory of Boston Lying-In Hospital; at Murphy General Hospital (Army); Brighton Marine Hospital (United States Public Health Service); at Boston City Hospital (in the Harvard medical and neurological services); Veterans Administration Hospitals Cushing, Bedford, Togus; Mental Hygiene Clinic; Ford Underwear Co., and General Electric Company, Lynn, Mass.

The method of this study consisted of a psychiatric interview and examination averaging two hours in length and the observation of the patient during a four or five day hospital stay. All examinations were conducted in privacy by one of us. During the interview, data were recorded on a standard questionnaire form comprising 106 items. All items were scored plus or zero in accordance with standard criteria established by us. The same criteria and scoring methods were used in recording relevant information from the questionnaire in the control groups studied.

Questions concerning symptoms considered improbable in hysteria were included to test whether these patients said "yes" to all questions, in order to determine if the examiners were suggesting the symptoms to the patients.[1a]

THE WOMEN CONTROL GROUPS

For control groups there were 50 working women from industry for healthy controls, 38 postpartum women from Boston Lying-In Hospital for hospital controls, and 30 women with chronic medical disease for sick controls from a diagnostic hospital.

Healthy Control Subjects.—Healthy control subjects were defined as including women who were regularly employed, who were not under medical care and did not consider themselves ill at the time of the interview. Sixty-two women were assigned to the study by a foreman. Of these women, 19.4 per cent did not agree to be examined. The examination was described as part of a medical research project, and the women were interviewed in privacy by one of us.

The 50 healthy control subjects were compared with the patient group with regard to the frequency of symptoms, number of hospitalizations and number and type of operations.

Control Subjects with Chronic Medical Illness.—The medically ill control subjects were interviewed and examined at the same hospital as were the women with hysteria and comprised a group of comparable age who had definitely diagnosed, chronic medical illness. Included in the 30 were those with diagnoses of ulcerative colitis, chronic duodenal ulcer, carcinoma of the bowel and stomach, Addison's disease, thyrotoxicosis, myxedema, Hodgkin's disease, rheumatic heart disease, diabetes and multiple myeloma. No neurological or psychiatric illnesses were included. The entire sample of 30 women was examined.

Sick control subjects were compared with the patient group with regard to nature of complaint, reason for hospitalization, manner and attitude toward illness and number of previous hospitalizations and operations.

Healthy Hospitalized Controls (Postpartum Women).—Hospital controls included 38 healthy women examined at Boston Lying-In Hospital during the postpartum period after a normal pregnancy. The whole group was examined. They were a group of healthy but hospitalized women who were used in the comparison of the manner and attitudes of well women in a hospital atmosphere with those of the women hysteria group. These patients were used further in an effort to answer the question: "Does hospital environment suggest, to a well woman, the symptoms of hysteria?"

MEN WITH DIAGNOSES OF "HYSTERIA"

The 38 men patients with diagnoses of "hysteria" were in service hospitals and had compensation prospects. Since no men with typical hysteria were discovered in civilian hospitals, and since "hysteria" is an acceptable diagnosis in service hospitals, men with this diagnosis were examined in these hospitals to ascertain what their clinical picture was. The 38 men included 20 soldiers on active duty, one member of the Coast Guard on active duty, 13 veterans and four civilian patients with compensation problems. The term "compensation" was interpreted in this study to mean that the patient had immediate prospect of tangible, material reward accruing from his illness, i. e., collecting money from pension or insurance sources, getting out of military service or avoiding arrest and prosecution. The word "compensation" was not used to mean any subtle factor not immediately obvious to a reasonable observer, such as obscure psychological gains or other less tangible or less immediate material gains. Although the presence of compensation factors was not a prerequisite for inclusion of any patient in the study, no men patients were found in whom this factor was not present. No patient with acute "combat (fright) hysteria" was examined. Criteria for accepting any men in this series are described in detail elsewhere.[2]

STATISTICAL ANALYSIS

The data obtained were analyzed statistically. The following statistical methods were used: The standard error of all proportions was calculated,[3] and the significance ratio of the difference between comparable proportions of various groups was calculated, using the standard formula $\sqrt{\frac{PoQo}{n_1} + \frac{PoQo}{n_2}}$ for the calculation of the standard error between proportions.[3] The standard error of all means was calculated, and the significance ratio of the difference between comparable means of various groups was calculated, using the formula $\sqrt{\frac{\sigma^2}{n_1} + \frac{\sigma^2}{n_2}}$ for the standard error of the differences between the means.[4] The significance ratio of the differences between the means of differences, i. e., correlated data, was calculated by the method presented by Lindquist.[5] Operation and hospitalization rates were calculated on the basis of 1,000 person-years. Odds corresponding to each significance ratio were taken from standard tables, as were squares and square roots.[6] All calculations were checked and rechecked.[7]

[1a] The details of the questionnaire used and the method of evaluating and recording data were described in Neurocirculatory Asthenia, Anxiety Neurosis, and Allied States, Interim Report 8, Office of the Surgeon General, Department of the Army, Washington, D. C., 1951.

CHARACTERISTICS OF WOMEN WITH HYSTERIA

Onset of Illness.—The illness began in early life. Age at onset of symptoms ranged from 11 to 33 years, with a mean age of onset of 19.1 years.

Symptoms.—There was a total of 1,153 complaints in the patient group, compared with 177 in the healthy controls; the number of symptoms ranged from 11 to 35, with a mean of 23 in the patients, and from zero to 13, with a mean of four, in the healthy controls.

TABLE 1.—*Symptoms in Fifty Women with Hysteria as Compared with those in Fifty Healthy Women*

Symptoms	Women with Hysteria, %	Healthy Controls, %	Significance Ratio

Easily upset	66	24	4.2
Depressed state	58	10	5.1
Nervousness	68	22	4.6

Patients with hysteria differed significantly from healthy control subjects with respect to the following symptoms: headaches, blurred vision, blindness, lumps in throat, palpitation, "anxiety attacks," anorexia, nausea, vomiting, urinary retention, menstrual difficulties, sexual difficulties, dizzy spells, faints, trances, paralysis and many others. These are shown in detail in table 1. Patients did not differ significantly from healthy control subjects in the frequency of the following three symptoms only: sleepwalking, 20 per cent vs. 8 per cent; loss of memory, 6 per cent vs. 0.0 per cent, and attempted suicide, 4 per cent vs. 0.0 per cent.

The following phenomena were investigated in both the hysteria group and the healthy group and were not significantly different: percentage of women who were arrested (hysteria group, 2 per cent; controls, 0.0 per cent; significance ratio, 1.0); percentage of women who used alcohol to excess (hysteria group, 2 per cent; controls, 0.0 per cent; significance ratio, 1.0), and percentage of women who had been divorced at least once (hysteria group, 28 per cent; controls, 11 per cent; significance ratio, 1.6).

Observations were made to determine whether hysteria patients appeared significantly younger for their age than other women. The hysteria patients averaged an estimated appearance of 1.3 years younger than their stated age, and the hospitalized healthy controls 0.2 years younger than their stated age and the controls with chronic medical illness 0.9 years older than their stated age. The differences in these values were not statistically significant (significance ratios: hysteria patients vs. healthy controls, 0.6; hysteria patients vs. medically ill controls, 1.6). Thus, women with hysteria were not found to be especially young-looking for their age; therefore, this is not a useful diagnostic sign of hysteria.

Some personal and social aspects of hysteria were investigated. Thirty-eight per cent of the hysteria patients, compared with none of the healthy controls, stated that they had had a significant amount of trouble with their schooling, either prolonged absences due to illness or impaired performance due to illness. This difference was statistically significant, with a significance ratio of 4.8. These patients had completed 11 years of school despite health troubles. This fact does not support the clinical idea that hysteria affects only the illiterate and feebleminded. Sixty-seven per cent reported a significant amount of trouble at work, either prolonged absences or impaired performance due to illness. This difference was statistically significant, with a significance ratio of 6.0. Fifty per cent of the women with hysteria, compared with 15 per cent of the healthy controls, had had a significant amount of marital trouble, either divorce, separation or active incompatability. This difference was statistically significant, with a significance ratio of 3.0.

Patients with hysteria not only complained of many symptoms but also described their symptoms in a characteristic manner. The descriptions were imprecise, vague, exaggerated, colorful and dramatic. In addition, when asked to describe in detail a specific complaint, these patients would shift the subject, so that they would be talking about an unrelated complaint or some seemingly irrelevant item in their past lives.

Thus, vomiting was described by a patient: "I vomit every ten minutes. Sometimes it lasts for two to three weeks at a time. Can't even take liquids. I even vomit water. I can't stand the smell of food." Food dyscrasia was described as, "I can't eat pastries. Always pay for it. I can't eat steak now. I throw up whole milk. I always throw up the skins of tomatoes. Pudding made with canned milk makes me sick. I have to use fresh milk." Trance state was reported: "I passed out on the bathroom floor during my period and was still on the floor when they found me the next morning." Variation in weight was described: "I can lose weight just walking down the streeet. I can hold my breath and lose weight. I was down to 65 pounds at one time."

Especially prominent symptoms were pain, menstrual difficulties, alleged difficulty during pregnancy and difficulty in sexual adjustment.

Pain was a more frequent feature of the illness in New England women than the paralysis, blindness and amnesia often assumed as most characteristic of the disease. There was a distinct contrast between the women patients and healthy women with regard to headaches, abdominal pain, pain in back and extremities and pain associated with menses and sexual intercourse.

Not only was there a high frequency of symptoms in women with hysteria associated with menstrual, sexual and reproductive functions, but also were such symptoms described by the patients in a characteristic, colorful and dramatic fashion. Thus, dysmenorrhea was described: "I can't work. Every month I am in bed for several days. I have had to have morphine hypos. There is a throbbing pain in the legs as if the blood doesn't circulate. Can't go to the bathroom, as I faint"; or, "It's murder! I want to die. It affects my nervous system." Patients reported amenorrhea and irregularities in the menstrual cycle as of frequent occurrence. One third of the patients described menstrual lapses of three months or longer, and 30 per cent described irregularity as a characteristic feature of their menstrual cycle. Excessive bleeding was a complaint in 44 per cent of the patients. It was frequently described dramatically as a hemorrhage or a bleeding in clots and lumps.

Sexual symptoms occurred in almost every case. Ninety-eight per cent of the women patients with hysteria presented sexual symptoms of some type. The most common of these was indifference. The patients reported: "Have never been interested," "It's not a normal thing to me. Disgusting!" or "My husband has never bothered me." To 70 per cent of the patients, as compared with 15 per cent of the healthy women, sexual intercourse was not a source of pleasure or satisfaction. Representative quotations from protocols included, "It's just a part of my married life and I have to do it," "I was always disappointed. Never really enjoyed it, but I had to please my husband" and "I have no feelings. It's just a duty." Sixty-three per cent of the patients, compared with 7 per cent of the healthy women, complained of dyspareunia. Patients reported: "Every time I had intercourse I swelled up on one side. It's sore and burns, and afterwards is very painful" or "I hate it. I have a severe pain on the right side and have to go to bed for a day."

Pregnancy in the women with hysteria was accompanied, according to their statements, by unusual difficulties. Fifty-six per cent of the patients, as compared with 5 per cent of the healthy controls and 8 per cent of the healthy postpartum women, described persistent vomiting beyond the third month of pregnancy. Labor and delivery were considered excessively difficult by 60 per cent of the patient group, compared with 20 per cent of the healthy women and 24 per cent of the postpartum women. Difficulties commonly described by the patient group included prolonged and unusually severe labor and a high proportion of high forceps deliveries.

Nature of Chief Complaints.—The illness was characterized by nonspecific and multiple chief complaints, the relevance of which was not clear (table 2). Despite the high frequency and dramatic quality of the symptoms it was remarkable that the reason for admission to a hospital was often vague or of doubtful relevance. Sixty-six per cent of the patients with hysteria, in contrast to 30 per cent of the women hospitalized with chronic medical illness, presented no specific chief complaint. Instead, in 48 per cent of the cases there was a welter of symptoms, which were classified as multiple complaints. In other cases the reason for admission presented by the patient was not clear, nor did they seem relevant. Thus, patients reported: "I am sore all over. Can't explain it. I have been sick all my life. Now I am alone since my husband died, and the doctor said I must come for help. It has taken $10,000 to keep me alive. This is my seventy-sixth hospitalization"; or "I have been taking care of my invalid mother, and I get very little rest or sleep," or "My father came here for a check-up on his diabetes and insisted that I come along. I had a nervous breakdown in 1943 and have never gotten around to being really well." These reports are in contrast to those of the chronic medically ill women patients, whose reasons for hospitalization and chief complaints were specific and seemingly relevant. Specific symptoms associated with hysteria, such as blindness, aphonia, paralysis and urinary retention, did not occur significantly in the chronically ill; nor were sexual symptoms prominent in women with actual chronic medical disease.

* The differences between hysteria patients and medical controls are all statistically significant.

† These values indicate number per person.

Manner and Attitude.—The manner and attitude of the patients with hysteria differed from that of the sick control subjects. Their past histories included, in addition to multiplicity of symptoms, dramatic incidents related to previous hospitalizations or happenings in their personal lives. The hysteria patients were more talkative, more friendly and ingratiating. Despite their friendly attitude toward the physician and their ease in discussing their illness, 76 per cent of the women patients felt that they had not been helped by any previous treatment.

Past History.—The past history of the patient with hysteria showed a significant excess in the number of previous hospital admissions and surgical operations when compared either with the medically ill or with the healthy control subjects (tables 2 and 3).

In patients with hysteria the total number of previous hospitalizations averaged 6.4 for each patient, as compared with 3.2 for the women with chronic medical illness and 1.2 for the healthy control subjects. There was a total of 321 hospital admissions in the patient group, as compared with 97 in the medical control group and 59 in the healthy control group. In brief, the woman patient with hysteria occupied a hospital bed twice as often as the woman with assorted medical illnesses, including such diseases as carcinoma or duodenal ulcer, and five times as often as the average healthy woman.

* These values indicate per cent.

The patients had undergone an excessive number of surgical operations. There was a total of 190 major operations in the hysteria group, as compared with 59 in the healthy control group. There was a mean of 3.8 operations for the hysteria group, as compared with 1.2 for the healthy control subjects and 2.0 for the medical control subjects. One patient with hysteria had 18 operations. Gynecologic operations, such as dilation and curettage, salpingo-oophorectomy or hysterectomy, were done in 72 per cent of the hysteria patients but in only 18 per cent of the healthy control subjects (totals of 83 gynecologic operations, as contrasted with 13 gynecologic operations). Nearly one fourth (24 per cent) of the women patients with hysteria had been sterilized with surgical procedure before the age of 35.

Appendectomy was done in 72 per cent of the patients, as compared with 28 per cent of the healthy control subjects; dilation and curettage were done in 42 per cent of the hysteria patients, as compared with 4 per cent in control subjects, and tubo-ovarian operations were done in 46 per cent of the women with hysteria and in 10 per cent of the control subjects.

Surgical operations performed on the women with hysteria involved removal of more than one organ in a significantly large number of cases when compared with those performed on healthy control subjects. There were 42 instances (a mean of 0.84 for each patient) noted in which the operations involved the appendix plus the tube or the ovary, or the gallbladder plus the appendix or the multiple internal female genital organs. For the group of healthy women six such operations (a mean of 0.12) were recorded. For example, the operation for acute appendicitis in healthy women is confined to appendectomy; in abdominal pain associated with hysteria exploratory surgery and removal of the appendix plus an ovary or some other organ was characteristic.

Minor surgical procedures such as cystoscopic examinations, removals of more than three teeth at a time, skin operations, skin suturings, cauterizations of turbinates and dilations of the rectum were also encountered in hysteria more frequently than in the control groups. The mean for these procedures was 2.0 for each patient, as compared with 0.3 for the healthy control subjects.

POSSIBILITY OF THE EXAMINER "SUGGESTING" SYMPTOMS TO PATIENTS

The question arose whether or not the examiner and the questionnaire suggest symptoms to the patient. To test this point the following questions as to symptoms considered by the examiner to be of unlikely occurrence in any group of patients were spaced through the questionnaire:

1. Has your hair turned white suddenly?
2. Do you have pain in the tip of the left ear?
3. Do you have pain in the right big toenail?
4. Has the skin on your thighs turned red?

Patients with hysteria did not show a high number of "yes" answers to these questions. No patient answered "yes" to questions 1 and 4; only 6 per cent of the patients answered "yes" to questions 2 and 3. Moreover, three symptoms (story of sexual assault, 10 per cent, amnesias, 6 per cent and attempted suicide, 4 per cent), which the investigators had expected to occur commonly as symptoms of hysteria, revealed only a few "yes" answers. This suggests that the examiner's attitude and inflection of voice in asking questions that he believed referred to common symptoms of hysteria were not the crucial factors in determining the frequency of "yes" answers.

COMPARISON OF HYSTERIA IN WOMEN WITH "HYSTERIA" IN MEN

Few men with this disorder were seen in the civilian hospitals, and those who were seen were "compensation cases." The illness as seen in the woman patient differed significantly from that referred to as hysteria in the men patients. Table 4 summarizes these differences.

The men patients presented a more specific and well defined chief complaint in contrast to the women, whose complaints were vague and nonspecific and in whom the reason for readmission to the hospital was sometimes not clear. The women with hysteria had a mean number of symptoms of 23, the men 11.

In the women patients the following 20 symptoms occurred with statistically greater frequency than in the men patients: double vision, lumps in throat, loss of voice, anxiety attacks, anorexia, food dyscrasia, abdominal pain, nausea, constipation, diarrhea, unusual variation in weight, sexual indifference, no sexual pleasure, painful intercourse, paralysis, paresthesia, faints, trances, crying easily and depressed state. There were no statistically significant differences in the following 17 symptoms: headaches, blurred vision, transient blindness, dizzy spells, dyspnea, palpitation, vomiting, back pain, joint pain, pain in the extremities, fits, sleepwalking, sleep talking, amnesia, nervousness, being easily upset and suicide attempts. Of these 17, the frequency was greater in 11 symptoms for the women and in only six for the men.[2]

Sexual difficulties were more prominent in the women than in the men, 98 per cent vs. 32 per cent. The past history of the women patients in 92 per cent of the cases included dramatic personal and medical happenings, as compared with 16 per cent of the men, and twice as many women patients had been subjected to major surgery (the mean number in the women was 2.8, as compared with 1.6 in the men).

The manner and attitude of the women patients was characterized by friendliness, affability and loquaciousness in describing symptoms, which was in contrast to that of the men patients.

A remarkably striking difference between the men and women patients concerned the possibility of immediate and obvious gain from illness or symptoms in the men (table 4). During the course of the study in a civilian hospital, either in the diagnostic hospital or in the medical or neurological services of a large municipal hospital, we were unable to find a case of hysteria in men comparable to the cases seen in women. In all of the men patients some factor of compensation was present. This factor was conspicuously absent in the women studied.

COMMENT

The data presented here show that women with diagnoses of hysteria in a civilian hospital presented a characteristic clinical picture. The symptoms are multiple, and most of the symptoms occur in most of the patients. The past histories of the patients show many hospitalizations and operations; the women with hysteria differ both from healthy control subjects and from patients with chronic medical illnesses in a myriad of ways. It is believed that the clinical picture is sufficiently characteristic and distinctive for practical use in everyday diagnosis. It should be pointed out that these patients were referred to a diagnostic hospital for diagnostic study, therapeutic advice, or because the physician thought a change might help. It is possible that these patients had a severer form of hysteria than the ordinary form. It is probable that these patients were doing poorly on a therapeutic regimen instituted by their physicians. The course of all hysteria therefore should not be inferred from these data. It is not known what proportion of patients with hysteria, well managed from the onset of their illness, would escape the severer manifestations of hysteria present in some patients of this group. The data do show, however, that hysteria does not invariably vanish as the patient grows older; there were seven patients 50 years old or older in the series. The maximum age was 57.

This report will not discuss the age old problem of hysteria in men. Suffice it to say here that no instances of hysteria in men were discovered in a civilian hospital, and that the "hysteria" diagnosed in men in the control study (those in service hospitals and with compensation problems) differed in many respects from the hysteria in women.[2]

The first important question arises whether or not the working definition of hysteria used in selecting these patients determined completely the results of the investigation. It is probable that this factor had some importance in the study but was not crucial. A clinical study of a disease, the cause of which is unknown and for which no quantitative objective diagnostic criteria are present, probably always amounts to the process of making more precise the original definition. However, it should be pointed out that the absence of certain specific features or pattern of features did not exclude a patient from this study. For instance, the examiners had the clinical impression before the study that features such as sexual frigidity, an excessive number of surgical operations, gastrointestinal pain, paralysis and visual difficulties were common features of hysteria. However, no patients were excluded from the study simply because they lacked these symptoms. The invesigators started with the general impression that monosymptomatic hysteria in civilian population probably does not occur. The problem of whether or not such cases should be included in the series did not arise, because no case presenting this problem was referred. The examiners started with the impression that hysteria in civilian men was rare or nonexistent but would have included such cases in the study if they had been discovered. Except for a few cases involving compensation and veterans' problems, no cases resembling the characteristic diagnostic picture of hysteria were seen in men in civilian hospitals; it was necessary to go to service hospitals in order to see adequate numbers of cases in men with what was labeled "hysteria." And, as noted previously, these service and compensation cases in men did not have the same clinical picture as cases of hysteria in women. It can and should be said that the original diagnostic criteria influenced in a general way the results of the study but did not determine the detailed results.

The second important question arises whether or not the women with diagnoses of hysteria in this study have the same disorder that other observers call hysteria. This question cannot be answered from the literature at this time, and it is probable that comparisons with past literature can never be made with finality. Almost the only authors who present quantitative clinical data about hysteria are Briquet[8] and Savill.[9] Even though the figures of this study are in good agreement with figures of these authors in most instances (table 5), the three studies are not strictly comparable, because the methods of eliciting data and definitions of symptoms were not clearly enough stated to be accurately reproducible by anyone. Except for these two studies there have been two predominant emphases in the literature concerning hysteria, namely, emphasis almost solely on the "neurological signs and symptoms," found chiefly in the writings of neurologists,[10] and emphasis almost solely on the psychological mechanisms called "conversion," "contraction of the field of consciousness" and specific "complexes." [11] The results of this study cannot be fruitfully compared with the results of studies done exclusively from the above points of view. Neither the predominantly neurological nor the predominantly speculative studies about psychological mechanisms have quantitative data, nor do the authors of such studies clearly state how their data were obtained. In addition, the data in the psychological studies are not presented in a form that is precise enough and sufficiently controlled to be reproducible by other workers.

[9] Savill, T. D.: Lectures on Hysteria and Allied Vaso-Motor Conditions, London, H. J. Glaisher, 1909.

In spite of these difficulties in comparing the present study with the remainder of the literature, there are apparent gross similarities between patients in this study and those reported elsewhere. Of six classical symptoms of hysteria, namely, paralysis, blindness, urinary retention, trances, fits and amnesia, 78 per cent of the patients in this study had at least one. Also, medical symptoms are noted in hysteria by other authors.[12]

No special study was made here of "stigmata" of hysteria, such as corneal anesthesia or pharyngeal anesthesia. Sir Arthur Hurst [13] believed that these "stigmata" did not occur spontaneously and concluded that they were probably suggested by the examiner. He created new "stigmata," namely, umbilical anesthesia, nasal anesthesia and the spiraling of the visual fields outward. In light of such data, no attention was paid to so-called classical stigmas in this study. The question arose, however, whether or not the examiners in this study were creating their own "stigmata" by suggesting certain symptoms to the patients in the questionnaire method. An attempt was made to control this factor by including four questions referable to symptoms that the examiners believed probably did not occur in hysteria, and it was demonstrated that the patients did not answer these questions affirmatively. From this it was concluded that the higher proportion of patients answering affirmatively about the symptoms of hysteria was not simply a reflection of the particular questions that were asked them.

TABLE 5.—*Prevalence of Symptoms in this Study Compared with Older Studies* *

* Twelve symptoms noted in this study but not by Briquet or Savill were not included in this table. Briquet and Savill mentioned 13 symptoms not specifically studied here, of which only chest pains, tremors and urinary frequency were said to occur frequently.

Many observers have suggested that the phenomena of hysteria arise through the process of suggestion.[14] Since it has been demonstrated that the examiners probably did not suggest the symptoms, it should be asked whether or not there are other reasonable possibilities that should be investigated. Are the symptoms of hysteria in New England reflections on the medical care, the health advertisements and twentieth century medical folklore that could be suggested to the patient through various mediums? If suggestion is an important part in hysteria symptomatology, as has been claimed,[10d] this might offer a plausible explanation of the origin of some of the symptoms; but there are no crucial data to support this, and controlled investigation would be necessary to find out.

16. (*a*) Freud.[11b] (*b*) Breuer and Freud.[11c] (*c*) Fenichel.[11d] (*d*) Kretschmer.[11e]

The question arises whether or not these patients might have some psychiatric disorder other than hysteria. The symptoms include those of anxiety neurosis (neurasthenia, neurocirculatory asthenia), but more and different symptoms occur in hysteria than in that disorder, according to the clinical picture described elsewhere.[15] During the time of this study the diagnosis of hypochondriasis was practically used not at all, and it is possible that in studies by others this diagnosis might have been used in some of the patients. The clinical features of that disorder are not clear to us. Finally, no evidence of serious psychiatric disease requiring institutionalization was elicited in the follow-up period. No other psychiatric diagnosis could be made reasonably in these patients.

It is believed that the symptoms presented here are characteristic of hysteria as it occurs today, and that this picture is probably what others have observed and termed hysteria. Other methods of diagnosing hysteria are in general use. Some clinicians rely on finding that the patient has a worry, problem or conflict. In our opinion this is so nonspecific that it is grossly unreliable. Other writers emphasize specific psychological "mechanisms" such as "conversion" or specific "complexes"[16] as important in the diagnosis of hysteria. These approaches have arisen largely from limited, uncontrolled observations on isolated cases, from speculation or from attempts to apply unproved theories and are not based on facts; in addition, the processes postulated are too complicated for ready clinical diagnostic purposes.

Some clinicians feel, furthermore, that the absence of a diagnosis or the presence of unexplained or peculiar symptoms or signs is an adequate basis for the diagnosis of hysteria; we believe that this method is grossly unreliable. Still other observers attempt to diagnose hysteria by trying to ascertain whether the symptoms and signs, neurological or otherwise, do or do not follow what they consider to be known "anatomic and physiologic boundaries." All these methods of attempting to diagnose hysteria fail to take into account the entire symptomatic clinical picture. Instead, they attempt to use some special theory or belief as to the nature of hysteria rather than apply the tested system of using history and physical examination in arriving at a diagnosis.

From the results of this investigation, it seems proper to suggest that the diagnosis of hysteria might be made by following the standard procedure used in the general field of diagnostic medicine: that is, determining the facts of the chief complaint, past history, physical examination and laboratory investigation. If the relevant symptoms of hysteria are known, this method can be applied by any physician without the use of special techniques, dream analysis or prolonged investigation of psychological conflicts. We believe that in our hands, and in the hands of residents and interns who have been instructed in these methods, this approach to hysteria has offered a useful tool for accurate diagnosis. It is suggested that the use of this method will allow the observer to diagnose hysteria when it really exists and to avoid making a false diagnosis of hysteria when it does not exist. It is further believed that this offers a sound basis for further clinical studies and for clinical investigation, which must always rest on the basis of accurate clinical observations.

These studies give no information about the cause of hysteria or about the specific mechanisms of symptoms. It is believed that these are unknown. Further, it is believed that they will be discovered by scientific investigation, rather than by the use of nonscientific methods, such as pure discussion, speculation, further reasoning from the dictums of "authorities" or "schools of psychology" or the use of such pretentious undefined words as "unconscious," "depth psychology," "psychodynamics," "psychosomatic," and "Oedipus complex," and that fundamental investigation must rest on a firm clinical basis.

CONCLUSIONS

1. From this study of 50 cases of hysteria in a civilian hospital it is concluded that hysteria probably has a characteristic clinical picture.

2. The age of onset was less than 35 years in all patients.

3. The disorder was seen only in women. It was concluded that, if patients with compensation, pension, insurance and service or veterans' problems were excluded, hysteria is seen rarely or not at all in men.

4. The illness was never monosymptomatic. No patient had fewer than 11 symptoms. The mean number was 23.

5. Characteristic features include lack of chief complaints, history of excessive surgical operations and hospitalizations, multiplicity of vaguely described present complaints, dysmenorrhea, sexual frigidity and dyspareunia, a friendly and overtalkative manner during the examination and a dramatic manner of describing past symptoms and illnesses.

6. The clinical picture of hysteria in civilian women is not the same as that seen in men with diagnoses of "hysteria" in service hospitals, or in patients, men or women, with obvious compensation and pension problems.

7. The conventional method of diagnosis employed in medical practice, that is, the use of history, examination and relevant laboratory data, seems equally applicable to the diagnosis of hysteria and seems preferable to attempts to use unproved psychological theories or complexes for this purpose.

8. As judged from a short term follow-up, this concept of hysteria and its diagnostic features seems reliable enough to warrant further clinical trial and to serve as a basis for further research.

Pregnancy and Diabetes.—Diabetes is a serious complication of pregnancy, in that the fetal mortality has been considerably higher than in normal pregnancy. In the past, mortality rates of infants have ranged between 30 and 50 per cent. The last decade, however, has witnessed a growing awareness on the part of obstetrician, internist and pediatrician of the problems inherent in pregnancy complicated by diabetes. As a result of increased knowledge and experience, fetal mortality has been lowered to the point where the physician may assure the average diabetic patient that pregnancy can be undertaken, with a good chance of delivering a live and healthy infant.—William P. Given, M.D., R. Gordon Douglas, M.D., and Edward Tolstoi, M.D., Pregnancy and Diabetes, *The Medical Clinics of North America*, May, 1951.

EVALUATION OF ADEQUATE ANTEPARTUM CARE FOR THE CARDIAC PATIENT

J. E. Fitzgerald, M.D., Augusta Webster, M.D., Bruce P. Zummo, M.D.,
and
P. C. Williams, M.D., Chicago

In reviewing the causes of maternal deaths in the Department of Obstetrics at the Cook County Hospital, we found that in an 11 year period only three women with adequate antepartum care had died of heart disease and its complications. In the same period however, 21 pregnant women with cardiac disease who had inadequate or no antepartum care died. This seemed to us significant enough to warrant a careful study of the value of antepartum care to pregnant women with cardiac disease.

The Department of Obstetrics at the Cook County Hospital has had a special clinic for pregnancy-complicating heart disease since 1925. In 1935 one of us (J.E.F.)[1] reported on 126 closely controlled pregnant women with heart disease. In 1937 Engbring and Sutton[2] reported on the clinic. There was one death from malignant endocarditis in these two groups of patients who had been under the constant direction of the prenatal cardiac clinic.

TABLE 1.—*Ages of Patients Referred to the Prenatal Cardiac Clinic*

Age, Yr.	Total	Per Cent
Under 20	269	26.12
20-29	529	51.36
30-39	191	18.54
40 and over	38	3.69
Not given	3	0.29
Total	1,030	100.00

TABLE 2.—*Cardiac Status*

Classification	No.	Per Cent		
Definite organic heart disease	460	44.66		
Normal hearts	88	8.54		
Functional group	482	46.80		
Systolic murmurs often complicated by arrhythmia			429	41.65
Miscellaneous, accounted for by symptoms, arrhythmias without murmurs			53	5.15

The material presented here covers an 11 year period, from July 1936 to July 1947. During this period 28,668 patients were admitted to the prenatal clinics, of whom 1,030 (3.59 per cent) were referred there for cardiac evaluation. These women were referred by the attending and resident staff of the obstetrical department of the hospital, the prenatal clinics of the Chicago Board of Health and the Infant Welfare Society and local practitioners.

The reasons for the patients' referrals were the following: histories of heart disease; symptoms of possible or probable heart disease, such as dyspnea, edema, tachycardia, chest pain or heart consciousness; presence of typical lesions, especially those of rheumatic heart disease; murmurs of unknown origin, and arrhythmias or clinical signs of hyperthyroidism. Of the 1,030 referred patients, 765, or approximately three fourths (74.27 per cent), were Negro, a ratio of 3:1, which corresponds essentially with the racial distribution of all antepartum admissions.

The length of observation varied from a single visit to repeated visits over a period of years. Two hundred and ninety-six women were observed for a period of one year or more, and, of these, 67 were observed for a period of five to 11 years.

Approximately one fourth (26.12 per cent) of the group (table 1) was below the age of twenty. One half of the group was in the 20 to 29 age bracket. In the third decade, the majority of patients referred were under the age of 35, and only 3.69 per cent were over the age of 40.

The number of children of each mother varied from one to four; the average was 2.53. This relatively low figure is due to the high per cent of primiparas (456 or 45.9 per cent) who attended the clinic.

INCIDENCE, TYPES AND DISTRIBUTION OF HEART DISEASE

Of the 1,030 patients studied, not all were found to have definite organic heart disease. Some were normal, while others manifested the functional heart of pregnancy syndrome.

The incidence of organic heart disease (table 2) in our 1,030 patients is 44.66 per cent, which is higher than the 25 per cent reported by Hamilton and Kellogg[3] and the 21.6 per cent of Engbring and Sutton[2] in similar studies. Some of the disparity is explained by the differences in the degree of criteria used to differentiate the organic heart disease from the functional heart disease of pregnancy.

The syndrome of functional heart disease has also been called gestatory heart disease. Anatomic changes due to increased cardiac work, added cardiac strain and rotational changes caused by the growing uterus are responsible for variations in sound, rhythm and such symptoms as palpitation and dyspnea. This syndrome presents a problem in diagnosis only during the last trimester. The differentiation of functional from organic heart disease is important from the standpoint of therapy and prognosis. Functional disturbances of the heart do not require any therapy other than reassurance and mild sedation.

The incidence of murmurs varies widely. In comparable studies Jensen[4] found values ranging from 0.71 to 75 per cent, with an average of 28 per cent; Sodeman[5] reported an incidence of 45 per cent, and Engbring and

Sutton[2] reported an incidence of 37.2 per cent. Our incidence was 41.6 per cent.

The distribution of the 460 organic heart lesions is shown in table 3. There were 426 (92.60 per cent) lesions of rheumatic origin, while 34 (7.4 per cent) constituted all other groups. This marked preponderance of rheumatic fever sequelae is easily explained by the well known tendency of rheumatic heart disease[6] to occur in the young.

Before we discuss this group further, it is desirable to give our interpretation of the terms involved. Following the lead of Engbring and Sutton,[2] we believe that the initial lesion in the valves is one of insufficiency or regurgitation. After approximately two years, stenosis takes place. Clinically the stenotic lesion is the predominant one. The term "mitral heart disease" is used to denote the presence of insufficiency and/or stenosis and, as such, is synonymous with the expression "double mitral."

Histories of rheumatic fever were obtained from 174, or 40.7 per cent, of the patients (table 4). This tends to confirm the findings of Edward Stieglitz[7] that half of the maternity patients with organic heart disease have no knowledge of the cardiac disorder prior to its discovery at the antepartum examination.

Syphilitic heart disease with positive serologic reaction was encountered in five instances. One lesion was of the aortic insufficiency type, and four were aortitis. All were treated, and the deliveries and puerperia were uneventful. The infants were free from infection during the period of observation. Two of these patients were 22 years of age, and the others were 34, 36 and 41 years respectively. The mean number of children was 2.5. There were no complications or deaths in this group.

Three instances of thyrotoxicosis associated with mitral heart disease were found. The typical symptoms of palpitation, tachycardia, heart consciousness, moist skin, nervousness, tremor and increased metabolic rates were noted in all three women. In one patient, who had undergone thyroid operations on two previous occasions, a complicating auricular fibrillation with a recurrence of toxicity developed, and she had to undergo a third thyroid operation. All three of these women were in the early thirties—further evidence that thyrotoxicosis elects the third decade as its most frequent time of appearance.

Hypertensive heart disease was present in 22 instances. In contrast to rheumatic heart disease, this condition was found in relatively older patients. The higher ratio of Negro to white patients also illustrates the tendency of that race toward hypertensive cardiovascular disease in the northern environment. The average age of this group on admission was 32 years.

Congenital heart disease was noted in three patients. They had disease of the patent ductus arteriosus type, as revealed by physical examination, fluoroscopy and roentgenography. Their ages were 14, 16 and 18 years respectively, and they had no history of decompensation. Only one knew of the presence of heart disease. Their labors were of average duration, and they were delivered of normal term infants, by means of episiotomy and low forceps while under pudendal block anesthesia. The puerperal courses were uneventful.

Coronary sclerosis was found in one patient. She was a 43 year old white multipara, who had been followed at another clinic for three years and was taking digitalis and potassium iodide. She had a history of recurrent attacks of dyspnea, with some precordial pain; there were findings of an apical systolic murmur, left ventricular enlargement, gallop rhythm and blood pressure of 120/90.

Auricular fibrillation beginning in pregnancy or puerperium was encountered four times. One patient was a Negro primigravida, 32 years of age, in whom the auricular fibrillation was associated with mitral heart disease and thyrotoxicosis. The second was a sextiparous, multigravid white woman, 31 years old, who was admitted to the Cook County Hospital because of early decompensation due to chronic rheumatic heart disease with auricular fibrillation. As soon as compensation was established, abdominal hysterotomy and sterilization were performed. She was discharged in a compensated state on digitalis therapy. The third patient was a uniparous, bigravid Negro, 30 years old, who was admitted to the Cook County Hospital when she was three months' pregnant; she had chronic rheumatic heart disease. There was slow fibrillation under digitalis management. This patient aborted spontaneously shortly after admission and refused sterilization. At her only postpartum visit she was in fairly good condition and in a compensated state. The fourth patient was a triparous, quadrigravid white woman, 31 years old, who was five months' pregnant and had mitral stenosis and auricular fibrillation. She was delivered of a full term infant uneventfully. One and a half years later, this patient was in good condition but still with slow fibrillations. The mean age of the fibrillating group was 30.6 years, and the average number of children was 2.6.

natal cardiac clinic. However, all these women, with three exceptions, were delivered safely.

During the same 11 year period, the records of the Cook County Hospital show that 55,938 mothers were delivered of viable infants and that the conditions of 704 of these women were diagnosed as organic heart disease. Furthermore, 24 maternal deaths were attributed to cardiac disease and its complications. There were 244 women with organic heart disease who were not seen in the cardiac clinic, and from this group there were 21 deaths. Most of these patients were considered as being of functional class 4 when they first came under our observation.

A summary of the fatalities demonstrates disasters which occur in the absence of adequate antepartum care (table 5).

SUMMARY OF FATALITIES

Fifteen of the patients who died had no antepartum attention whatsoever. Two patients visited local maternal agencies but once and were referred immediately for hospitalization; one died six days after admission, and at autopsy vegetative and verrucous endocarditis of the mitral valve was revealed. The other died 27 hours after admission, with a clinical diagnosis of aortic regurgitation, double mitral lesion and possible patent ductus arteriosus.

The two patients who are said to have been under the care of family physicians entered in a serious state. One patient was seven months pregnant and presented a picture of auricular fibrillation, mitral heart disease and severe decompensation. She died undelivered, five hours after entrance, and permission for autopsy was denied. The second patient was eight months pregnant and died eight days after admission; at autopsy chronic rheumatic heart disease with renal disease was revealed.

Those who attended the Cook County Hospital Clinics only once fared as follows: One entered at term, delivered spontaneously and died 50 days later of subacute bacterial endocarditis. On admission her cardiac lesion was mitral stenosis of rheumatic origin. The second patient, a 23 year old uniparous, secundigravid white woman, entered at term with complaints of backaches, chills and fever, nausea and vomiting. A loud systolic murmur was heard over the entire precordium, but no evidence of decompensation was noted. On the third day of hospitalization, abdominal distention occurred and Levine suction gave no relief. A roentgenogram of the abdomen revealed a greatly distended bowel. It was felt that emptying of the uterus would relieve the distention, and therefore, a successful bag induction was done. The patient was delivered with low forceps while under pudendal block anesthesia eight hours after the bag was placed. She failed to improve, however; her downhill course continued, and she died 24 hours post partum. The clinical impression was endocarditis and bilateral hydrothorax. Multiple emboli producing pulmonary and mesenteric infarction were considered the causes for the chest and abdominal symptoms. Permission to perform an autopsy was denied.

Each of the three patients listed as having had adequate antepartum care died after abdominal hysterotomy. The first patient had a four months pregnancy complicating a rheumatic heart condition. She was a 21 year old biparous trigravida, with a long-standing history of cardiac disease. An abdominal hysterotomy was done, and she died eight days later. At autopsy were revealed old rheumatic endocarditis, obliterative pericarditis, multiple septic infarcts in spleen and kidneys and a recent embolus in the pulmonary artery and the lower lobe of the right lung. The second patient had a 10 week pregnancy complicating a subacute bacterial endocarditis. Hysterotomy was done, and she died 15 days later of sepsis and vegetative endocarditis. The third patient was a 35 year old quintiparous, sextigravid woman, with a long-standing history of cardiac disease, who complained of mild dyspnea, weakness and pressure over the precordium. These complaints had been noticed since the onset of pregnancy. Cardiac findings were those of aortic insufficiency. Abdominal hysterotomy and sterilization were done. Three days postoperatively, a left hemiplegia developed. Six days postoperatively, she suddenly became dyspneic and cyanotic and died. Permission for autopsy was not granted. On a clinical basis. the cause of death was considered to be pulmonary and cerebral embolism.

These three patients demonstrate that the pregnant patient with cardiac disease is not a good surgical risk. All three were considered to be in a state of compensation when operations were performed. The first two patients, who were operated on in 1937 and 1938, might have had a better opportunity for recovery in this day of chemotherapy, antibiotics and abundant blood. In all three instances the cardiac condition was such that the hazard of continued pregnancy would also have been great.

In the entire series of 704 patients with organic heart disease, the pregnancy was interrupted in only eight instances. Before surgical intervention, each patient was hospitalized until a maximum degree of compensation was obtained. Three of this group died, and their cases have been discussed above. The remaining five made uneventful recoveries.

ANALYSIS OF MORTALITY FIGURES

In analyzing the mortality figures, one must remember that the total number of fatalities is small. Accordingly, the figures may be misleading. In general, it is accepted that age definitely influences the outcome of the pregnancy complicating heart disease. The older the patient, whether pregnant or not, the greater is the possibility of a cardiac breakdown.

Gravidity and parity per se have no influence on the outlook for the woman with heart disease, and with careful management the expectancy of life should not be shortened (Engbring and Sutton,[2] Oppel [8] and Jensen [4]).

According to Gorenberg and McGleary,[9] most of the deaths occur during the first eight months of pregnancy; however, death may occur at any time (Stander,[10] Jensen,[11] Stromme and Kuder [12]). Our figures corroborate those of Gorenberg and McGleary.

It is an accepted fact that once a patient is in a decompensated state, she becomes a poor obstetrical risk (table 6). The more frequent the decompensation, however mild, the greater the danger of cardiac death. In this series of 24 deaths, two patients had been in decompensated states before these pregnancies; one of the two died of bronchopneumonia complicating a severe preeclampsia, and the other entered the Cook County Hospital in shock from a ruptured ectopic pregnancy. She was operated on but failed to recover. At autopsy a hemorrhage from a vessel in the posterior portion of the right broad ligament, vegetative endocarditis of the median aortic leaflet and anemic infarcts of both kidneys were revealed. Six patients had been in a repeated decompensated state during these pregnancies and died. Fourteen were in a decompensated state for the first time and died. Two records failed to reveal a past history of cardiac disease. It would seem from this series that cardiac decompensation in a pregnant woman is more serious than that in a nonpregnant woman.

Previous decompensation, not recurring with this pregnancy	2
Previous decompensation, recurring with this pregnancy	6
Decompensation for the first time with this pregnancy	14
Not recorded	2
Total	24

Since 92.6 per cent of our patients had symptoms of rheumatic heart disease, it is only natural that the complications associated with this disease predominate as the most frequent cause of death. Accordingly, the presence of endocarditis was proved at autopsy in 15 cases, and in one case it was diagnosed clinically. There were five deaths attributed to acute failure of chronic rheumatic

heart. Auricular fibrillation was present in two patients; in one it was associated with rheumatic heart disease, and in the other it was associated with a fatal pulmonary embolus.

MANAGEMENT OF THE PREGNANT PATIENT WITH CARDIAC DISEASE

The management of the pregnant woman with cardiac disease should begin long before the onset of gestation. It should date back to the day of her initial illness. Marriage and pregnancy call for reevaluation of her cardiac functional capacity. The pregestational classification of her cardiac status offers a good index of what may be expected.

During pregnancy a study should be made of the patient's functional capacity; she should then be classified in one of the four classes specified by the American Heart Association and her activities regulated accordingly. We utilize a dietary regimen which supplies food essentials and which at the same time avoids causing digestive distress. Usually it is low in caloric value, salt and fat, moderate in carbohydrate and high in protein. Every effort is made to keep the patient's total weight gain at 20 pounds (9.1 Kg.) or less.

The barbiturates are used freely in this group of patients. Digitalis is not employed routinely and quinidine seldom and only when indicated. Should digitalization appear necessary, the patient is hospitalized for study and treatment.

Bed rest is encouraged. All patients are asked to rest one hour and preferably two each afternoon. They are instructed to sleep at least eight hours each night. Bed rest constitutes the most effective single therapeutic agent in the treatment of heart disease. One of us (J. E. F.) [1] reported that absolute bed rest reduced the incidence of decompensation in pregnant patients with cardiac disease from 22.3 to 2.5 per cent. Gorenberg [13] stated that absolute bed rest reduced the maternal mortality rate from 3.5 per cent to 0.64 per cent. According to Claha,[14] decompensation during labor and the puerperal period occurs about five times as frequently in women who have inadequate bed rest as it does in those who have frequent and prolonged rest periods.

Functional class 1 patients usually do not require hospital care until the onset of labor. Class 2 patients are admitted at the time of diagnosis and are hospitalized until they become class 1 and are then followed in the prenatal cardiac clinic. These patients are subsequently hospitalized one week before their expected date of delivery. Class 3 and class 4 patients are admitted promptly for study and treatment. The patients with severe cardiac disease are hospitalized for the remainder of the gestational and puerperal periods or until compensated.

In our opinion the patient with cardiac disease may be safely delivered from below, if there is no obstetric contraindication. The cardiac condition per se does not necessitate a cesarean section. On rare occasions, however, surgical intervention may be necessary because of obstetrical complications. We do not agree with the contention that section is less hazardous to the damaged heart than a well managed normal labor. Cesarean section adds the burden of laparotomy as well as its potential complications of ileus, sepsis, thrombosis and embolism. Gorenberg and McCleary [10] have shown that the morbidity and mortality rates are higher when cesarean section is employed. Pregnant women with cardiac defects are exceedingly poor surgical risks. Therefore, whenever possible, one should allow the baby to deliver through the natural and safest route, through the vagina.

The cardiopath in labor requires constant vigilance, with particular attention devoted to pulse and respiration. Morphine or meperidine (demerol®) hydrochloride with scopolamine hydrobromide is used routinely. Digitalis and oxygen are added if the pulse rate is over 110 a minute and the respiratory rate is over 24. The second stage of labor is conducted so that it is as short as possible, but at all times undue manipulations are avoided. A low forceps delivery is done as soon as obstetrical conditions are present. Pudendal block anesthesia and adequate episiotomy are routine.

Care of the cardiopath does not cease with delivery. We have seen women deliver without difficulty and later show signs of decompensation. Sepsis is especially guarded against. Mild sedation is maintained, and longer periods of bed rest are required than for normal women. No patients are discharged until compensation is established. They are released with full instructions on dietary and therapeutic management and requested to report to the cardiac clinic two weeks after discharge for subsequent follow-up care and observation.

SUMMARY

1. The study covers the management of 704 mothers with organic heart disease out of a total of 55,938 women delivered of viable infants in an 11 year period at the Cook County Hospital.

2. Of the 24 maternal deaths in cardiac patients reviewed, only three patients had adequate antepartum care.

3. The value of antepartum care in the pregnant cardiac patient is demonstrated.

Say Not Too Much, Speak It Gently.—Your conduct in the sick-room, in conversation with the patient or his friends, is a matter of very great importance to their welfare and to your own reputation. . . . Say not too much, speak it gently, and guard it cautiously. Always remember that words used before patients or their friends are like coppers given to children; you think little of them, but the children count them over and over, make all conceivable imaginary uses of them, and very likely change them into something or other which makes them sick, and causes you to be sent for to clean out the stomach you have so unwittingly filled with trash; a task not so easy as it was to give them the means of filling it. The forming of a diagnosis, the utterance of a prognosis, and the laying down of a plan of treatment, all demand certain particular cautions.—Oliver Wendell Holmes, Currents and Counter Currents in Medical Science, Boston, Ticknor & Fields, 1861, p. 399.

Vol. 146, No. 10

PHYSIOLOGIC THERAPY FOR URINARY STRESS INCONTINENCE

Arnold H. Kegel, M.D., Los Angeles

Poor control of the bladder outlet is observed in approximately 5.5% of all adult women.[1] To the patient the condition is always embarrassing, often humiliating, and at times incapacitating. In the past patients with more advanced urinary stress incontinence were treated by surgical intervention, with results that were not always satisfactory. But little could be done for the great number of women with slight or moderate complaints. As operation is not indicated in such cases, temporizing procedures had to be applied that all too often resulted in dissatisfaction of patient and physician alike. In the meantime, however, it has been demonstrated that in the overwhelming majority of cases,[2] even with a history of childbirth injury, urinary stress incontinence is due to inherent weakness of the muscles surrounding bladder neck and vagina. This condition is amenable to correction through reeducation of muscular function and resistive exercises that can be instituted as a simple office procedure.

PHYSIOLOGIC CONSIDERATIONS

The physiologic therapy of urinary stress incontinence was developed as the result of experience gathered in several thousand examinations carried out over a period of 14 years preceding 1946. These examinations of the pelvic outlet, however, differ in one important respect from the usual gynecologic investigation. Early in my studies it had become apparent that presence or absence of muscular function had an important bearing on the status of the pelvic outlet, and, accordingly, the degree of contraction that could be elicited through voluntary action was determined in every case.

On the strength of such routine examinations for function, it has been possible to establish the fact that in all patients suffering from simple urinary stress incontinence the voluntary muscles in the region of the vesical neck show evidence of loss of function and atrophy, often simulating a degree of paralysis. This impaired status of the neuromuscular structures can only in exceptional instances be traced to congenital anomalies or to disease of the spinal cord but is generally due to failure to develop a normal action pattern early in life.

The process is most pronounced in the pubococcygeus muscle, which is the largest and strongest of the five diaphragms forming the pelvic floor.[3] Gainey [1] reported atrophy of the levator group in 31% of 1,000 postpartum patients who had received excellent obstetric care. In a series of 300 patients suffering from various degrees of incontinence, I noted lack of function and atrophy of the pubococcygeus muscle in all, including 24 nulliparous women and two patients who had been delivered by Caesarean section. It is obvious that in the latter instances lack of function cannot have been caused by injury of the genital hiatus. Also, when the early histories of 100 primiparae and multiparae with a complaint of urinary stress incontinence were closely studied, it was found that in at least 29 instances weak control of the bladder outlet had definitely existed prior to the birth of the first child. All this indicates that the condition described constitutes a distinct functional entity, which it is proposed to call the "syndrome of lack of awareness of function and coordination of the pubococcygeus muscle."

It is the predominant function of the bladder to collect and retain the urine, while the urethra acts primarily as a canal for emptying the bladder. In normal women the mechanism for holding urine in the bladder without conscious effort and for voiding under voluntary control depends upon balanced reflexes of the neuromuscular tissues situated at the juncture of vesical neck and proximal urethra. Such balance of the reflexes is maintained by the pubococcygeus muscle with its visceral extensions, which have been described in detail by Curtis and Anson.[4] Control of the bladder outlet, it is true, is not impaired in all women with faulty function of the pubococcygeus muscle. However, it has been established beyond any doubt that loss of function of the pubococcygeus muscle is present in all women with true urinary stress incontinence.

EXAMINATION

Examination of patients for functional deficiencies of the muscles of the genital hiatus consists of observation, palpation, and measurement of the strength of contractions. The patient is placed into the lithotomy position and requested to draw up, draw in, and retract the perineal muscles. Since many patients do not understand these instructions, they are asked to contract as though to check a bowel movement or stop the flow of urine. It is then observed whether this effort results in retraction of the perineum and, especially, of the meatus.

One finger is introduced into the vagina, and its entire circumference is palpated, especially at the level of the middle third. The patient is instructed to repeat the contractions and also to contract the vaginal muscles upon the examining finger. The result of each single effort to contract is carefully noted, and it will be found that in about 60% of all women normal contractions occur. In more than 30% of women, however, no contractions, or only weak or delayed contractions, can be elicited in spite of diligent efforts. Patients with urinary stress incon-

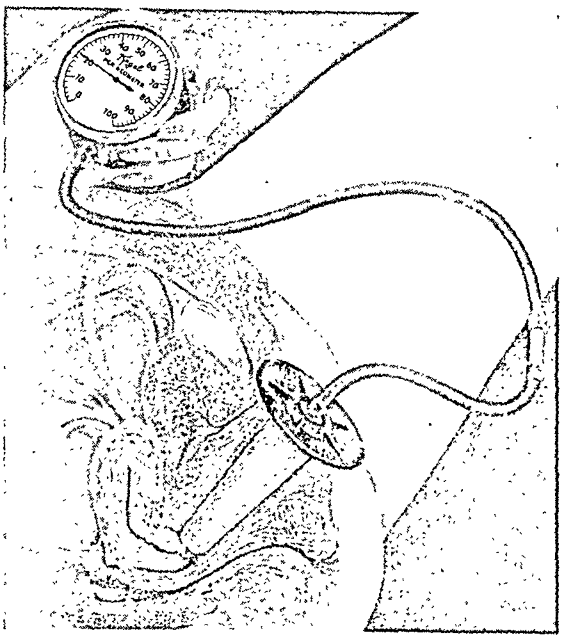
tinence often remark that they had *not* known that voluntary contraction of these muscles is possible.

Lack of function of the pubococcygeus muscle is ordinarily accompanied with atrophy that becomes apparent to the palpating finger as marked roominess of the vagina in all directions, immediately within the introitus or at the level of the middle third of the vagina. Usually the walls are thin and bulging, show poor tone, and are freely movable, as if detached from their surrounding structures, conditions generally diagnosed as cystourethrocele or moderate degrees of uterine prolapse. In patients suffering from urinary stress incontinence, slight tensing or weak contractions of the pubococcygeus muscle may or may not be felt in the anterior quadrant of the vagina; however, even the slightest contractions elicited are of importance in physiologic therapy. Residual function is most frequently observed in the posterior quadrant of the perineum and usually involves the superficial pillars of the levator ani. Contractions of the posterior plate of the levator sling may also be palpated behind the rectal pouch, and tensing of these muscles can often be traced to their origin in the os pubis.



The Perineometer, showing the resistance chamber in position, connected with a manometer for visual guidance in muscle education and resistive exercises of the pubococcygeus muscle. (Instruments for this study were supplied by the Perineometer Research Laboratory, Los Angeles 5.)

Further findings of prognostic importance include diastasis of the pubococcygeus muscle as well as unilateral atrophy due to injury.

The strength of contractions is estimated from the impression gained through palpation or is actually measured with the aid of the Perineometer (Figure). This instrument consists of a pneumatic resistance chamber to which a manometer designed to register the strength of contractions of the muscles surrounding the vagina is attached. In women with normal function of the pubococcygeus muscle the reading will amount to 30 to 60 mm. Hg, while in patients with urinary stress incontinence muscular function is poor or absent, and the manometer registers a pressure of 0 to 5 mm. Hg.

In order to obtain correct measurements, it is necessary that the patient confine her efforts at contractions only to the muscles in the region of perineum and vagina. Patients with lack of awareness of function of the pubococcygeus muscle will invariably try to substitute contractions of extraneous muscles, especially those of the abdominal wall and gluteal region.

THERAPY

Perusal of seven current textbooks on obstetrics and gynecology failed to reveal any mention of active exercises for the relief of urinary stress incontinence. Miller[5] has advocated teaching women to tense their sphincter mechanisms in order to prevent urinary stress incontinence in later life. According to Davies,[6] patients with urinary stress incontinence who present no gross anatomical injuries should be trained to develop the voluntary muscles of the urethra by interrupting the urinary stream during the act of voiding and through contractions during coitus. The crucial importance of the pubococcygeus muscle, however, has not been fully appreciated, and the therapeutic method described in the following is, as far as is known, the first attempt to train this muscle specifically in order to improve sphincteric function of the vagina and bladder outlet.

Physiologic therapy is divided into two phases: muscle education and resistive exercise.[7] The only way in which a patient can become aware of her ability to contract muscles that she has never before used voluntarily is through association with other muscular functions in the neighborhood of the pubococcygeus muscle, which are already under conscious control. While the palpating finger is over the pillars of the pubococcygeus, the patient is requested to contract the muscles of which she is cognizant, and a tensing of the pillars may be felt in most cases on exertion of strong efforts as though to stop a bowel movement, to stop the flow of urine, to retract the perineum, or to squeeze the palpating finger. It is made certain that the patient understands clearly which specific effort leads to tensing of the pubococcygeus, and she is instructed to repeat exclusively these contractions. In the course of frequent repetitions of these efforts over a period of weeks, the strength of contractions will increase and the patient will establish conscious control of the pubococcygeus muscle. The procedure may be compared with the effort to teach a left-handed person to use the right hand, or, for that matter, to teach wiggling of the ears with the aid of a mirror.

While voluntary contractions alone will increase the strength and improve the function of the major components of the levator sling, they have little effect upon the extensions of the pubococcygeus muscle, which interdigitate and insert into the intrinsic musculature of the walls of the proximal urethra and middle third of the vagina. These small fibers, however, which evidently are closely related to the sphincteric mechanisms of the bladder neck and its functions, must be exercised through contractions extending over the entire circumference of the vagina. It is the purpose of the Perineometer, the main part of which consists of a resistance chamber of anatomic conformity, to serve as the object against which such squeezing contractions of all vaginal muscles can be exerted. Both muscle education and resistive exercises are facilitated through visual control of the effort exerted, and for this purpose a calibrated manometer has been attached to the cylindrical diaphragm.

[7] Jones, E. G.: Role of Active Exercise in Pelvic Muscle Physiology, West. J. Surg. **58**: 1-10 (Jan.) 1950.

After the physician has made sure that the patient contracts the correct muscles and understands how to use the Perineometer, she is instructed to maintain a routine of adequate exercises—20 min. three times daily, or a total of 300 contractions. A weekly check of the patient's efforts is essential; in the beginning of therapy the majority of patients are, as a rule, not using the right muscles and, therefore, need careful reinstruction. It is, furthermore, highly important that undue fatigue be avoided.

CLINICAL COURSE AND RESULTS

The clinical course and results of therapy [8] vary in two groups of patients. In urinary stress incontinence of the simple type, i. e., in cases in which partial control exists and the patient becomes incontinent only with coughing, sneezing, or straining, prompt improvement, usually in a few weeks, is the rule, while complete relief is observed after six to eight weeks. Urinary stress incontinence of the simple type is very frequent, and in the present series of over 500 cases more than 75% of all patients belonged in this category. In the past such women tolerated this annoying and embarrassing condition, with all its possible undesirable psychological effects, because they felt that it was not serious enough to warrant surgical intervention. With the introduction of physiologic therapy, a quick, reliable, and conservative method of treatment has been developed for a condition for which no suitable therapy had existed heretofore.

A different type of response was noted in women with incapacitating urinary stress incontinence of a degree that in the past had been usually treated by surgical intervention. Most of these patients had for many years worn pads to absorb the urine and had practically lost their normal reflexes of urination. In this subgroup of 146 cases, furthermore, 66 women had been subjected to surgical measures involving the anterior vaginal wall, and these same patients had additionally undergone 60 major pelvic operations. In spite of this, complete relief was obtained by means of physiologic therapy alone in 84% of all instances. The remaining 16% with partial relief or failure included patients with such complicating factors as multiple surgical failures, senility, diabetes, obesity, and mental deficiency. True stress incontinence is distinguished from incontinence due to neurological disease and urge incontinence traceable to upper urinary tract lesions.

Ordinarily it proved difficult to teach women with incapacitating urinary stress incontinence awareness of function of the pubococcygeus muscle, and in some instances various methods of instruction had to be employed over a year's time before voluntary contractions of the muscle could be established. In those patients who had undergone radical surgical procedures in the region of the urethra, resistive exercises had to be continued for a longer time before symptomatic improvement could be observed, and in some instances the result remained incomplete. In all types of urinary stress incontinence, however, full and lasting relief may be expected only if the patient does not stop resistive exercises as soon as the first improvement is noted, but continues with the same diligence until not only function has been restored but a strengthening of the supportive and sphincteric structures becomes palpable. Such restoration of tone and function in muscles of the pelvic outlet is comparable with the results observed in other neuromusculofascial structures after specific active exercises.

In this brief presentation of physiologic therapy for the treatment of urinary stress incontinence, it was obviously not possible to touch upon all aspects of the complex subject. It should, however, be mentioned that in the treatment of "symptomatic cystocele" urinary stress incontinence is first relieved by physiologic therapy and the cystourethrocele is repaired subsequently. Contraindications for physiologic therapy are negligible, and in no instance was the condition aggravated; some of the most gratifying results were obtained in debilitated women in the eighth decade of life. The most important application of the new method may be prophylactic treatment of women with poor function of the pubococcygeus muscle, especially in the prepartum and postpartum periods, and also before and after all types of plastic operations involving the sphincteric and supportive structures of the pelvic outlet.[9]

Initial results of this therapeutic plan are so encouraging that examination for function of the pelvic muscles is recommended as a routine procedure in all obstetrical and gynecologic patients.

SUMMARY

The physiologic therapy of urinary stress incontinence is a simple and reliably successful office procedure, especially useful for early and moderately advanced cases for which no suitable conservative treatment has existed up to now.

In women with true urinary stress incontinence the muscles of the region of the vesical neck show evidence of loss of function and atrophy. The pubococcygeus muscle possesses visceral extensions that interdigitate with the musculature of the bladder neck. Tone and function of the muscles of the pelvic outlet can be restored through muscle education and active exercises of the pubococcygeus muscle.

Examination and active exercises are facilitated by the use of a specially devised instrument, the Perineometer.

In a series of more than 500 patients continence was restored in 84%. In 70% urinary stress incontinence was of the simple type, the remaining cases being complicated by various factors.

METACHRONOUS CARCINOMAS OF THE COLON

Fred W. Rankin, M.D.
and
A. B. Conger Jr., M.D., Lexington, Ky.

Metachronous cancers of the large bowel are unique enough in occurrence to be considered almost bizarre. Ewing and Boyd, among others, formerly believed that one carcinoma developing in a person conferred a certain immunity that prevented another primary carcinoma from developing, in contradistinction to a recurrence or a distant metastasis. As late as 1930, Lockhart-Mummery [1] stated that there seemed to be sufficient clinical evidence to support the belief that one malignant growth inhibited the development of a second malignant lesion. However, more recently, with the increasing number of reports [2] of multiple cancers occurring simultaneously (synchronous carcinomas) and with an interval of time between (metachronous carcinmas), an almost diametrically opposite opinion has been thought to be correct. Indeed, Brindley [3] has gone so far as to state that "a patient with one cancer is a good subject for the development of a second, and is more susceptible than one who is cancer-free."

In 1945 Berson and Berger [2e] collected from the literature 66 cases with two, and six cases with three, cancers of the large intestine, to which group they added 13 cases of two cancers and three cases of three malignant growths of the colon. This is strong evidence to support the thesis that the polyps that appear in many colons are the basic factors in cancers of this portion of the alimentary canal.

Synchronous cancers have been relatively common in our experience, particularly in the group of cases termed "familial polyposis." With the increasing development of diagnostic facilities and a better understanding of the pathology involved, it is not rare to find more than one malignancy in the large bowel. The corollary of this statement seems obvious: namely, that one should suspect multiple malignancies and should at least examine the rectum and entire colon prior to an operation for cancer of the lower portion of the gastrointestinal canal. Usually, one does not give a barium sulfate enema to a patient with cancer of the rectum. Experience has taught us, however, that the use of the enema before examination should be routine, except when one fears the production of an acute intestinal obstruction by the opaque medium.

There seems little reason for the surgeon to overlook a second synchronous lesion at operation, and yet this does happen, as is pointed out by Berson and Berger,[2e] who remark, "Unquestionably, many poor results (in the treatment of carcinoma of the large intestine) can be attributed to the fact that a second lesion was missed," and by Norbury,[4] who suggests that a number of cases of so-called recurrence after operation are really due to the presence of another primary lesion. Warren [5] has estimated that the incidence of multiple primary malignancies may be as high as 6 per cent, and we are inclined to agree with him after considerable experience in this field.

Our interest in metachronous malignancies has been stimulated by the fact that we have had, in the past few years, seven patients who have undergone second operations for carcinoma of the large bowel a number of years after removal of a primary carcinoma of either the rectum or the colon. A review of these cases follows.

REPORT OF CASES

Case 1.—W. F. M., a 49 year old white man, was operated on by one of us (F. W. R.) at the Mayo Clinic on May 30, 1930, for a carcinoma of the sigmoid. An obstructive resection was done. The pathologist's diagnosis was grade 1 papillary adenocarcinoma with perisigmoiditis and abscess formation without glandular involvement. The patient was perfectly well for 19 years but was admitted to St. Joseph Hospital, Lexington, on Sept. 23, 1949, with a history of pains in the right side for 10 days. At operation, a large carcinoma was found at the hepatic flexure. The pathological diagnosis was adenocarcinoma and papilliferous mucoid carcinoma, grade 2, in the right colon, with extension into the surrounding fat but without involvement of the lymph nodes. The postoperative course was uneventful, and the patient has been well since.

Case 2.—P. S., a 47 year old white man, was operated on for carcinoma by one of us (F. W. R.) on Dec. 18, 1931, at the Mayo Clinic. The pathologist's diagnosis was grade 1 papillary adenocarcinoma of the rectosigmoid. No glandular involvement was found. A combined abdominoperineal resection was done. The patient was well for 15 years but was admitted to St. Joseph Hospital on Sept. 26, 1946, with a history of mild abdominal discomfort for 18 months. At operation a carcinoma of the cecum was found and removed. The pathologist's diagnosis was large adenocarcinoma of the cecum, grade 2, without glandular involvement. The patient is well at the present time.

Case 3.—A. F. T., a 55 year old white physician was admitted to St. Joseph Hospital on Jan. 31, 1942, and a combined abdominoperineal resection was done for an adenocarcinoma, grade 2, in the rectum, without glandular involvement. The patient was well for seven and one-half years.

On Nov. 22, 1949, while irrigating his single barrel colostomy stoma, he noted a moderate quantity of bright red blood. Examination of the colon after a barium sulfate enema, on November 25, revealed a filling defect in the cecum. On December 2, Dr. A. S. Graham performed a hemicolectomy around to the middle of the transverse colon and reestablished the continuity of the bowel. The pathologist's diagnosis was colloid adenocarcinoma of the cecum, grade 3. The patient is well at present.

Case 4.—W. B., a 46 year old white male teacher, was operated on at St. Joseph Hospital by one of us (F. W. R.) in December 1940. An abdominoperineal resection of the rectum was done for an adenocarcinoma, grade 3, without glandular involvement.

The patient was well for nine years but was readmitted on Sept. 7, 1949 with a history of occasional bleeding from the colostomy stoma for three months before admission. At opera-

tion about 30 cm. of colon proximal to the stoma was resected. The pathologist's diagnosis was adenocarcinoma of the colon, grade 2, without glandular involvement. The patient is well at present.

Case 5.—S. R., a 50 year old housewife, was first admitted on May 3, 1948, to St. Joseph Hospital, where a combined abdominoperineal resection was done for a grade 2 adenocarcinoma of the rectum without glandular metastases. The patient was well for approximately two years.

She was readmitted on Feb. 15, 1950, with a history of severe constipation and the discharge of bright red blood during the previous few weeks. At operation a resection of bowel proximal to the stoma was done for a large adenocarcinoma of the descending colon, grade 4, without glandular metastasis.

Case 6.—J. M., a 61 year old white man, was first admitted to St. Joseph Hospital on July 4, 1935, when a combined abdominoperineal resection was done for a grade 2 adenocarcinoma of the rectum. Three polyps were found in the specimen in addition to the carcinoma, but there was no glandular involvement.

The patient was well for 15 years but was readmitted on Jan. 11, 1950, with a history of constipation and bleeding from the colostomy stoma. At operation a segment of large intestine proximal to the site of the colostomy was removed. It contained a large grade 2 adenocarcinoma from the midportion of the transverse colon and a grade 1 adenocarcinoma in the descending colon, in addition to many adenomatous polyps of the mucosa, without glandular involvement. The patient is well at the present time.

Case 7.—H. T. L., a 42 year old white man, was operated on at St. Joseph Hospital by one of us (F. W. R.) in 1933 for carcinoma of the rectum. A one stage combined abdominoperineal resection was done. The pathologist's diagnosis was adenocarcinoma, grade 2, and polyposis of the rectum, without glandular metastasis.

The patient was perfectly well for 13 years and did not come in for follow-up study during this time. He was readmitted on April 27, 1948, with a history of some prolapse of the colostomy stoma for four or five years and a visible growth on the prolapsed mucosa. On April 30, a portion of large bowel proximal to the stoma was resected, with the specimen showing extensive polyposis in the segment of colon with some polyps showing precancerous hyperplasia. An examination after a barium sulfate enema previous to operation had shown no other polyps, but six months later a repeat examination showed multiple polyps in the cecum. On Jan. 21, 1949, a resection of the remainder of the colon was done for multiple carcinomas [6] of the right colon and cecum, grade 2, with local metastasis.

COMMENT

In every case of multiple carcinoma, there is always some question as to whether the second carcinoma is a new carcinoma, a metastasis or a recurrence of the old one. When Billroth made the first report of multiple carcinomas, in 1889,[7] he set forth some postulates which he thought must be fulfilled before multiple carcinomas could be identified as independent lesions. They are, briefly, as follows: (1) The two growths should differ histologically; (2) Each growth must spring from its parent epithelium, and (3) Each growth must be regarded as responsible for its own group of metastases. Actually, it is impossible for these postulates to be fulfilled in a living patient with two carcinomas of the large bowel, neither of which has metastasized, and Bunting [8] made the statement that, in his opinion, these posulates were meant to apply only to malignant growths arising in different organs. In 1932, Warren and Gates [6] broadened the original postulates as follows: "Each of the tumors must present a definite picture of malignancy, each must be distinct, and the possibility of one being a metastasis of the other must be excluded."

In the cases presented above, each tumor was malignant, each was distinct and, as best we know, the possibility of one being a metastasis of the other has been excluded. Time must be of some importance in this instance, and the fact that these patients were completely well for periods of 2, 7, 9, 12, 15 [8] and 17 years should be of considerable significance, as should be the fact that no other metastases were found at operation or have been discovered so far. This latter helps to fulfil the fourth postulate added by Mercanton,[9] in 1893, to Billroth's original three. He believed that "if, after removal of the two carcinomas, the patient remains free from the disease, the two growths must have been independent else there should have been other metastases." However, too little time has passed since the removal of the second carcinoma for this judgment to apply to our six living patients. Suffice it to say that, with the evidence we have, the second carcinomas were new carcinomas and not recurrences or metastases of the original lesions.

Discussions and theories on the etiological factors of cancer of the large bowel are always interesting and frequently productive, and the exciting work now being carried out by Craigie [10] in England brings the virus hypothesis once again into the foreground. Andrewes [11] has recently made these comments:

> We have noted, in considering viruses of many kinds, how often a virus latently infects its host until a jolt to the virus cell equilibrium brings about visible disease. We have seen how transmissability of a virus, ability to infect the cells, is a varying property that may or may not be present. We have found that virus infection may begin in utero and possibly be transmitted in the germ plasma. Finally, viruses are capable of great feats in the way of variation and adaptation, and they can also cause cell proliferation. We have, therefore, no grounds for maintaining that viruses cannot cause cancer because viruses do not have the qualities necessary to act the part. We need not find it difficult to believe in viruses that are almost ubiquitous, normally cause no visible disease, are transmitted in earliest days of life and only in certain circumstances sustain a jolt that causes them to give rise to new growths.

Certainly this idea answers some questions and is reasonable, but a great amount of work needs to be done before one is justified in accepting it.

At the present, we feel justified in making this statement: Most carcinomas of the large bowel originate in polyps or have polyps as their earliest manifestations. In case 7 presented above, it was apparent from the beginning that the patient had multiple polyposis. He refused to come in for follow-up visits until he had carcinoma in several of his polyps some 15 years later. His father died of "bowel trouble" at the age of 65. No other member of his family has ever had a known malignancy. However, this patient could presumably be included in the class of persons with so-called congenital polyposis.[12] The other six cases are most easily explained by saying that these patients were "polyp formers" and that a second polyp was present at the time of the original operation or developed later, eventually becoming malignant.

Buie [13] has recently stated that "probably 12 to 14 per cent of persons more than 40 years of age have polyps of the colon. One of every 10 persons in this age group has a polyp which can be discovered on proctoscopic examination, and all polyps of the colon are carcinomas or will become carcinomas if they are not destroyed and if the patient lives long enough."

Experience with these cases, six of which have come to our attention in the last two years, as well as the literature, indicate that in every patient who has one cancer of the large intestine a second malignancy may develop many years after the first one.

We believe strongly that every patient who has had a successful removal of a carcinoma of the colon should be seen at least every six months to a year thereafter for the rest of his life. This has been emphasized by several authors,[2e] but it cannot be reiterated too often. At each follow-up visit, a proctoscopic examination and an examination after a barium sulfate enema should be done, in addition to the usual check for metastases. The proctoscopic examination should be done through the colostomy stoma if the rectum has been removed. A double contrast study for polyps not visible at proctoscopy should be done at the time of the examination after a barium sulfate enema. The tannic acid technic, as reported by Wyatt and his colleagues [14] at the meeting of the American Roentgen Ray Society in Cincinnati, October 1949, has been found helpful in showing polyps. In a painstaking search for these, every advantage should be utilized.

It has been our experience that an adequate examination after a barium sulfate enema cannot be done on the same day as a proctoscopic examination, unless there are a fairly long interval and several enemas between the two examinations to remove air put in by the proctoscope. In all, the patient spends only two full days in the hospital each six months unless a lesion is found. This is a small price to pay for continued life and health. If a polyp or new growth is found, obviously it should be radically and rapidly treated.

SUMMARY AND CONCLUSIONS

Seven cases of new carcinoma of the large intestine following resection done two to 18 years previously are reported. The following points are emphasized in the comment regarding these cases:

1. The patients in the cases presented obviously had metachronous carcinomas rather than recurrences or metastases.
2. The incidence of multiple primary malignancies is much higher than is generally realized.
3. We believe that a patient with one cancer is a good subject for the development of a second and may be more susceptible than one who is cancer-free.
4. Suggestions are made regarding follow-up examinations of patients with carcinoma of the large intestine. For the rest of the patient's life, an adequate proctoscopic examination and a roentgen examination after a barium sulfate enema should be done at regular intervals of six months to one year.

PNEUMOPERITONEUM IN THE STUDY OF PELVIC STRUCTURES

J. R. Maxfield Jr., M.D., Dallas, Texas

Pneumoperitoneum is a simple and relatively harmless procedure. Since Alvarez [1] introduced the use of carbon dioxide, in 1921, as the gas for pneumoperitoneum, many hundreds of pneumoperitoneum studies have been made throughout this country with but few untoward effects.

As a means of roentgenologic diagnosis, pneumoperitoneum was proclaimed by Case [2] in 1921 to be one of the instances of roentgenologic progress. He called this procedure "the most brilliant diagnostic accomplishment in the last five or six years of roentgenological development."

Excellent scientific papers by Stewart and Stein,[3] Stein and Arens,[4] Lewis,[5] Sante,[6] Faulkner,[7] Stein,[8] Peterson,[9] Martin,[10] Rubin [11] and others have not been able to popularize this excellent diagnostic procedure.

There is still considerable hesitancy on the part of radiologists to develop pneumoperitoneum as a part of their diagnostic procedures. Perhaps this is due to the fact that the contraindications and dangers of induced pneumoperitoneum have been overemphasized. There should be no real danger from this technic in the hands of capable radiologists. The technical features of producing pneumoperitoneum have been thoroughly covered by Stewart and Stein,[3] Lewis,[5] Rubin,[11] Decker,[12] Maxfield and McIlwain,[13] and others. Use of carbon dioxide as the gas for distending the abdomen eliminates the danger of air embolism. The only real contraindications seem to be definite cardiac insufficiency and acute infections. Elevation of the diaphragm by pneumoperitoneum might impose an additional load on an overburdened heart and might thus prove disastrous. The activation of acute infection seems unlikely but might conceivably occur. In our clinic we have used pneumoperitoneum without any evidence of trouble in cases of chronic peritonitis, subdiaphragmatic abscess, pelvic inflammatory disease, chronic bacterial endocarditis and bilateral pleura effusion.

Pneumoperitoneum should be available in all leading roentgenological departments. This will require the en-

[1] Alvarez, W. C.: Use of CO₂ in Pneumoperitoneum, Am. J. Roentgenol. 8: 71 (Feb.) 1921.

dorsement of the roentgenologist, surgeon, internist and gynecologist. It should not be used in lieu of other diagnostic measures; rather, it should be used in conjunction with other clinical and laboratory procedures in those cases in which the diagnosis is obscure. It may confirm clinical impressions when other data are not sufficient for clearcut diagnosis, or it may completely change the clinical impressions.

Pneumoperitoneum is an accurate method of diagnosis enabling the radiologist to study the size, shape and position of liver, spleen, kidneys and pelvic viscera, to determine the presence, extent or absence of abdominal or pelvic adhesions, to study the pelvis, abdomen and retroperitoneal areas for presence of masses or tumor implants and to identify intrauterine or abdominal pregnancy.

It has long been known that accurate information can be obtained in this manner that is not available by other diagnostic means.

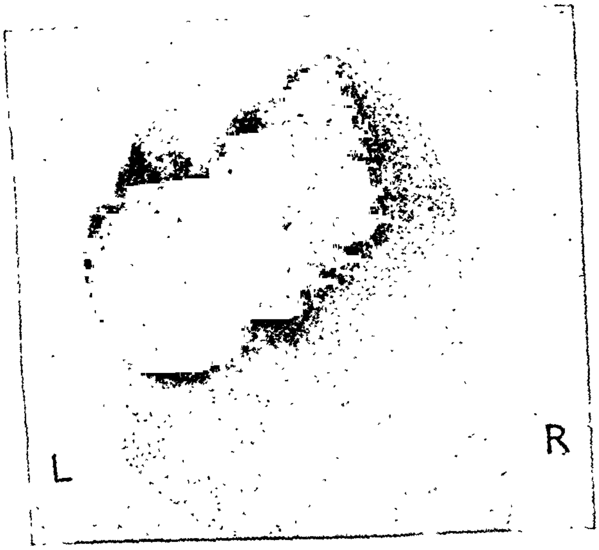

Fig. 1.—Roentgenogram showing enlarged right ovary and absence of left ovary. The uterus and bladder are adherent.

Stein has long been an ardent advocate of pneumoperitoneum in the study of pelvic structures. In his scientific presentations during the past 30 years, he has repeatedly written "that no test is so valuable as the transabdominal pneumoperitoneum." It is surprising that this procedure is not more widely used by the leading gynecologists and radiologists in the larger centers. Stein has mentioned that most of these patients are first seen by the gynecologist, and that the gynecologist does not feel the need for roentgenographic corroboration because, as a rule, he is satisfied with a diagnosis achieved by means of a history, speculum and bimanual examination.

The purpose of this paper is again to call the attention of the radiologists and gynecologists to the value of pneumoperitoneum. This can best be done by the presentation of case reports; these will follow a brief discussion of a few points on preparation of the patient and on the technic.

I feel that it is important to prepare the patient by explaining to her the procedure that she will go through and the sensations she will encounter during the examination. I have found little psychic trauma to patients. Most of them are cooperative and have not resisted repetition of the procedure when it was necessary.

Further, the use of pentobarbital (nembutal®) or secobarbital (seconal®), 1½ grains (0.10 Gm.), one hour before the procedure and the use of methadon hydrochloride, 10 mg., with atropine, 1/150 grain (0.40 mg.), 15 minutes before the start of the procedure adequately prepares the patient.

The simplicity of the apparatus with which pneumoperitoneum is induced and the technic of the process have been thoroughly described in previous papers by many authors. I claim no originality for the method used in pneumoperitoneum. The use of a blunt 18 or 20 gage spinal needle is the best means of penetrating the anterior abdominal wall. Most authors agree that the ideal site for penetrating the anterior abdominal wall is 1 inch (2.5 cm.) below and 1 inch to the left of the umbilicus. There are surprisingly few times when this space is not clear and easy to penetrate. For patients who have had numerous operations or in whom there is a history of peritonitis, with the possibility of adhesions to the anterior abdominal wall, I prefer to make the puncture with the patient lying down on her left side so that the needle can be put through the right lateral abdominal wall over the liver. In this way the possibility of damage to the bowel structure can be eliminated. The natural falling away from the chest and the abdominal wall of the heavier structures in the abdomen and the position of the bowel below it make it almost impossible to cause any damage. Once the needle is free in the abdominal cavity, 2,000 cc. of carbon dioxide is injected, and the films are taken immediately on withdrawal of the needle.

The first case to be reported illustrates the information made available by this method.

Case 1.—Mrs. I. M. C., aged 30, gave a history of an operation in 1944 with left salpingo-oophorectomy, appendectomy and uterine suspension. Since that time she had had trouble with her bladder. Her present complaint was pain in the right lower

quadrant, usually dull but sometimes sharp. She was not sure about aggravation of pain at menstrual periods, which were fairly regular and of heavy flow. She complained of premenstrual tension for three to four days before her period. Recently she had complained of a heavy feeling in the right lower quadrant, with dizziness. Pelvic examination revealed a small cervix, scarred, without evidence of a break in the mucosa. The uterus was twice its normal size, held up by suspension and deviated to the right with fibroids. Physical examination showed her to be otherwise normal.

Pneumoperitoneum revealed a large right ovary (fig. 1) and a uterus 1.5 times the normal size and bound tightly to the urinary bladder. The surgeon reexamined the patient and still insisted that a fibroid uterus accounted for shadows seen on pneumoperitoneum. At the operation a chocolate cyst of the right ovary was found, approximately 10 cm. in diameter. The uterus was slightly enlarged, with the fundus adherent to the peritoneum of the anterior abdominal wall; this condition was apparently the result of an old operation.

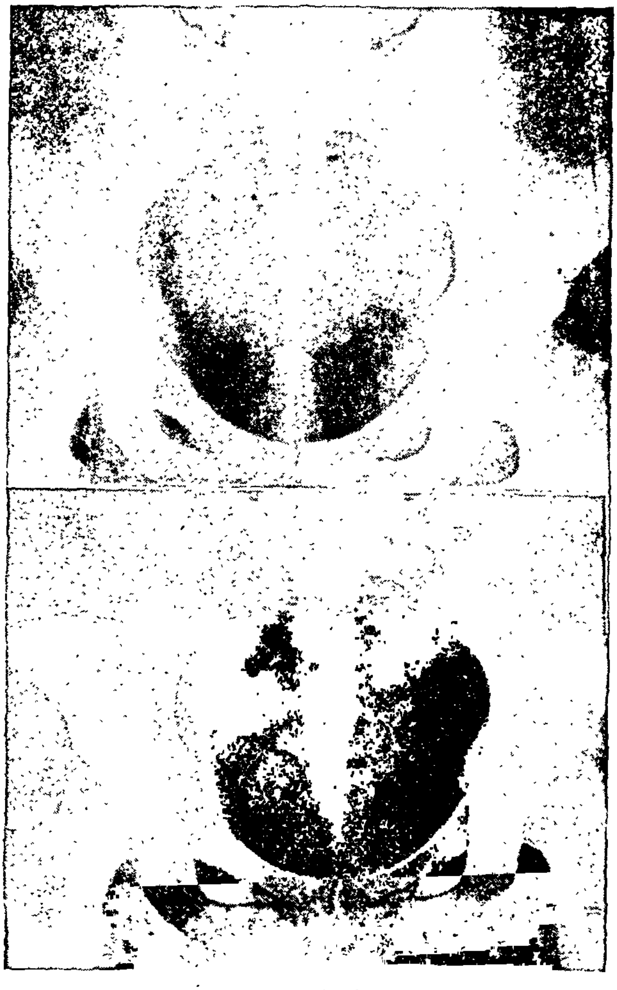

Fig. 2.—Films of patient's pelvis showing uterus depressing bladder. There are no demonstrable soft tissue masses in lateral portion of pelvis.

Case 2.—Mrs. J. S., aged 45, was treated in August 1948 for grade IV epidermoid carcinoma of the cervix, League of Nations stage III. The immediate result following radium and roentgen therapy was good, and the patient was symptom free until October 1949, when she began to have painless swelling of the left leg. Examination of the left leg showed it to be twice the size of the right one. No evidence of lymphadenopathy could be found in the inguinal region, and no venous thrombosis was present. Pelvic examination revealed a thick left broad ligament with extensive fibrosis, but no nodular mass could be found. Rectal examination revealed essentially the same findings. The anterior and posterior pelvic portals showed the evidence of previous radiation treatment usually seen in patients treated in this manner. The point in question was whether this was due to radiation fibrosis or due to an active tumor causing obstruction to the leg. Survey films of the chest, abdomen and pelvis and an intravenous pyelogram (figs. 2 and 3) revealed no demonstrable

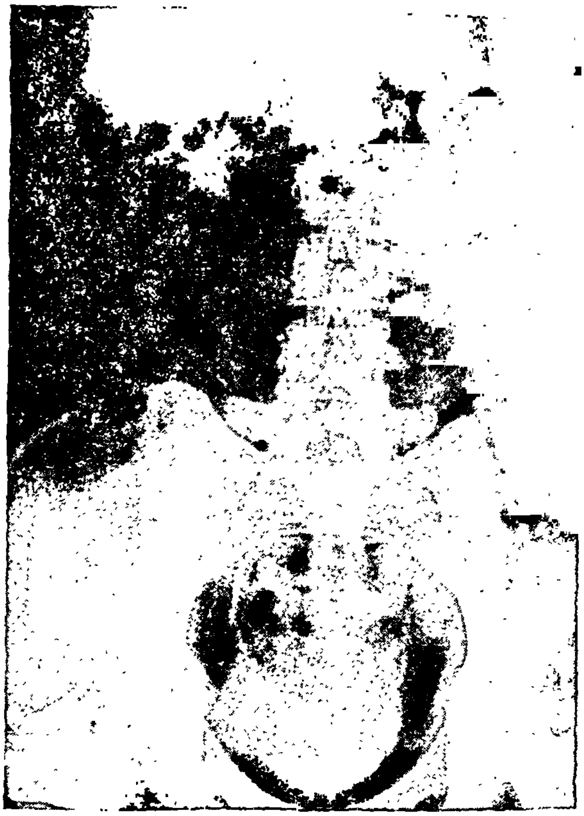

Fig. 3.—Intravenous pyelogram giving indication of normal kidney function. Ureters are normal, without displacement or dilatation. The uterus depresses dome of well filled bladder. There is no evidence of soft tissue masses in the lateral portion of the pelvis.

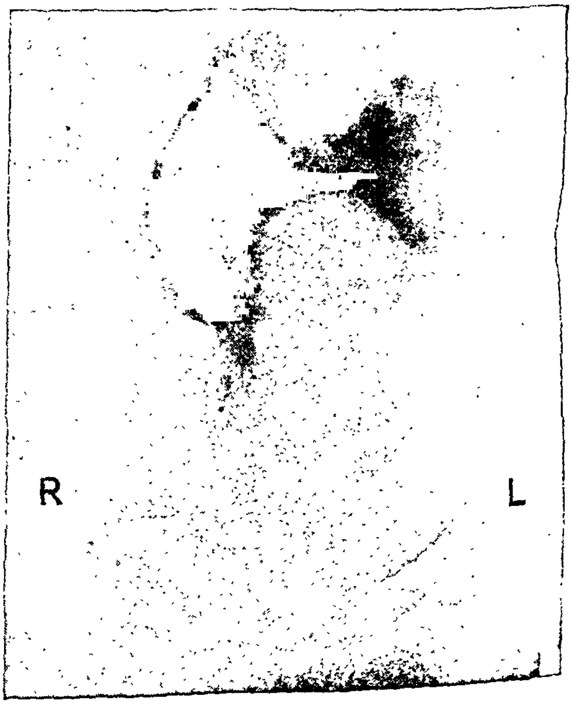

Fig. 4.—Pneumoperitoneum shows normal right side of pelvis. The uterus is slightly enlarged and drawn to the left. There is a nodular mass in the left side of the pelvis indicating carcinoma metastasis.

pathological changes in soft tissue or bony structures. Pneumoperitoneum (fig. 4) revealed the right side of the pelvis to be normal. The left side showed a nodular mass of tissue indicating a tumor growing in the lymph nodes and causing obstruction to the lymphatics of the left leg. As a result of this information, further intense roentgen therapy was given, and the swelling promptly disappeared.

These are only two cases from the series that I have been privileged to examine, but they indicate the importance of the information that this procedure will produce.

SUMMARY

In summary, I feel that pneumoperitoneum offers a method of determining the size, shape and position of pelvic structures so that accurate evaluation of clinical information can be made. This is an accurate method of determining intrauterine or ectopic pregnancy without interrupting the pregnancy. This is a method for evaluating progress and determining treatment of patients with malignant disease in the pelvic structures.

Pneumoperitoneum should be more widely used as a diagnostic aid in the leading centers of this country.

ABSTRACT OF DISCUSSION

DR. JOHN O'SULLIVAN, Melbourne, Australia: How much air does Dr. Maxfield inject?

DR. FRANK J. RIGOS, Tacoma, Wash.: What position does he use for the roentgen examination?

DR. J. MAURICE ROBINSON, San Francisco, Cal.: I should like to ask whether he uses carbon dioxide instead of air.

DR. J. R. MAXFIELD JR., Dallas, Texas: I apparently left out more than I should have on the subject of technic. These technics have been described in several papers. The amount of carbon dioxide (and that is the gas that should be used in all of these, because one can eliminate the possibility of danger by using carbon dioxide) is approximately 2,000 cc. This does not cause undue discomfort to the patient. A patient who has marked ascites, in which there has been the previous removal of fluid, will tolerate 4,000 or 5,000 cc. without difficulty. The positions that I use routinely for pelvic structure study are the right lateral decubitus and the left lateral decubitus, with the head down at a Trendelenburg position of 15 degrees. The patient is then turned to the prone position, with the table inclined to 45 degrees and the beam inclined downward through the pelvic strait, so that the patient's pelvis is up, the head is down and the beam goes through at an angle to outline pelvic structures. In this position the structures seem to have the gas around them for the best contrast. Dr. Irving Stein, in his numerous writings, has described the technic in which a knee-chest position is used. A special table has been made so that the patient can actually be in a knee-chest position in which the pneumogram of the pelvis can be taken. However, I feel that one should encourage the use of pneumoperitoneum in the general radiological laboratories. It can be done on the standard tables, and excellent films can be obtained without great difficulty to patient or radiologist. The paper has numerous bibliographical references that will describe the use of pneumoperitoneum in detail. The apparatus to induce it is quite simple and is also described in previous papers.

Infectious Mononucleosis.—There is no specific therapeutic agent for infectious mononucleosis. Sulfonamides and penicillin may benefit a complicating streptococcus throat infection. Convalescent infectious mononucleosis and scarlet fever sera have given dramatic results in some seriously ill patients. Human plasma and gamma globulin have occasionally appeared to be beneficial. Aureomycin and Chloromycetin seem effective in some cases when started early in the disease. Hepatitis is extremely common, and when severe should be treated exactly like cases of infectious hepatitis.—Robert E. Kaufman, M.D., Treatment of Infectious Mononucleosis, *American Practitioner,* April, 1951.

CLINICAL NOTES

METHEMOGLOBINEMIC CYANOSIS

REPORT OF AN EPIDEMIC DUE TO CORNING EXTRACT SUBSTITUTED FOR MAPLE SYRUP

Jay Tepperman, M.D.
Robert Marquardt, M.D.
George H. Reifenstein, M.D.
and
Eugene L. Lozner, M.D., Syracuse, N. Y.

Sudden onset of cyanosis is an alarming event that usually suggests a cardiovascular or pulmonary catastrophe. A rarer cause is acute toxic methemoglobinemia. We recently had an opportunity to study an "epidemic" of the latter condition involving at least seven patients. All had eaten wheatcakes and "maple syrup" at a diner. This report briefly summarizes the case histories and describes the series of events leading to discovery of the offending agent. A similar epidemic of methemoglobinemia due to accidental nitrite ingestion was reported by Greenberg, Birnkrant and Schiftner,[1] who reviewed the literature up to 1945. At that time, they called attention to the serious nature of the poisoning and mentioned the high fatality rate. At least 19 deaths due to sodium nitrite have been reported. Since Greenberg's article appeared, the therapeutic use of methylene blue for cyanosis has been established beyond doubt. Although five of our seven patients in the present series were not particularly ill and recovered spontaneously, the remaining two patients appeared moribund on hospital admission. In these two patients, methylene blue was employed intravenously and appeared to be lifesaving.

REPORT OF CASES

CASE 1.—C. C., a 37 year old male taxi driver, was admitted to the ward service of the Syracuse Memorial Hospital at 9:15 a. m. on May 15, 1950, because of severe pounding of the heart and increasing bluish discoloration of the skin of one hour's duration.

At 7:30 a. m. on this day, the patient had pancakes and syrup at a diner in Syracuse. He thought the butter tasted rancid. At 8:15 a. m. he became nauseated and vomited small amounts of food. Shortly thereafter, dizziness, palpitation and cyanosis developed. At 6:15 on the morning of admission, he had taken one tablet of a commercial headache preparation and for 48 hours before entry he had been taking acetylsalicylic acid. He also stated that in the course of his occupation he had to wear dark trousers because the dye from the seat covers of the taxi was apt to stain his trousers and his skin.

Physical examination on admission showed the patient to be conscious but markedly cyanotic and dyspneic. His blood pressure was 120/70, temperature 99.8 F., pulse rate 140 and respiration rate 22. Except for the cyanosis and a few rales over the left lower lung field, the entire examination was

---

From the Departments of Medicine and Pharmacology, State University of New York, Medical Center at Syracuse, School of Medicine, and from the Department of Health, City of Syracuse.

Dr. Jaime Paris assisted in the clinical management of the first patient. Mr. Richard Wilson and Mr. Melvin Rossman, of the class of 1951, aided in collecting the samples of food which permitted the identification of the toxic substance. The following physicians permitted us to report their patients: Dr. S. Schwartzbart, case 2; Dr. S. Schwartzberg, case 3; Drs. W. Saile and J. G. F. Hiss, case 5.

[1] Greenberg, M.; Birnkrant, W. B., and Schiftner, J. J.: Outbreak of Sodium Nitrite Poisoning, Am. J. Pub. Health 35: 1217-1220 (Nov.) 1945.

noncontributory. His heart and lungs showed no abnormality on physical examination.

Laboratory Data.—On admission, the patient's hematocrit reading was 49 per cent, and his leukocyte count was 11,500, with 67 per cent polymorphonuclear cells, 1 per cent monocytes, 1 per cent eosinophils and 31 per cent lymphocytes. Results of urinalysis were normal. The nonprotein nitrogen concentration was 42 mg. per 100 cc. and the fasting blood sugar level was 110 mg. per 100 cc. On the day after admission his leukocyte count was 14,000 with 70 per cent polymorphonuclear cells.

Hospital Course.—On admission the patient was placed in an oxygen tent, but despite this his cyanosis increased. At 10:15 a. m. he became irrational; his blood presure fell to 70/50. He then fainted and had minor generalized convulsions. After he was placed in the Trendelenberg position, his rationality returned, and he complained of tingling of his hands. This process was reversed by raising his back, and then he would faint. Blood was drawn at this time, and it appeared grossly to be of dark chocolate color. Oxygen bubbled through it did not change its color, and a clinical diagnosis of methemoglobinemia was made. At this time, 100 mg. of methylene blue was administered intravenously. Immediately before administration of the methylene blue, blood was drawn for a methemoglobin determination according to the method of Evelyn and Malloy.[2] Methemoglobin was estimated to be present in the amount of 75 per cent of the total pigment. Twenty minutes after the administration of the methylene blue the tingling had disappeared from the extremities and the man became rational. Fifty minutes after the administration of methylene blue the methemoglobin concentration was 60 per cent. Cyanosis was definitely less. The blood pressure was 100/70. Three hours after the administration of methylene blue, cyanosis could not be detected clinically but the methemoglobin concentration was reported as 18 per cent. Another 100 mg. of methylene blue was injected intravenously at this time, and thereafter all signs and symptoms improved. He was discharged from the hospital on May 19. An electrocardiogram taken when the patient's methemoglobin concentration was 75 per cent showed sinus tachycardia with slight RS-T segment depression in leads V_4, V_5 and V_6. Two days later the electrocardiogram was entirely within normal limits.

The etiological factors considered in this case on the day of admission were acetanilid, aniline dye and sodium nitrite or nitrate adulteration of the food. The overwhelming nature of the methemoglobinemia and the rapidity of its onset following the morning meal suggested that the offending toxin was most likely a nitrite and that the patient had ingested it with his breakfast. However, no steps were taken to identify the toxic agent until after the admission of the second patient.

CASE 2.—H. R., a 54 year old telephone lineman, was admitted to the Crouse-Irving Hospital on May 16, 1950, at 11:00 a. m., complaining of a faint feeling and dyspnea of three hours' duration. This man had been in excellent health until the morning of admission, when, after a breakfast of pancakes and syrup at 8:00 a. m. at the same diner as the first patient, he suddenly became nauseated and felt "numb" and had generalized tingling. He then became weak and dyspneic, staggered and then fainted. A physician was called who found him extremely cyanotic, dyspneic and disoriented and referred him to the hospital.

Physical examination showed the patient to be comatose with marked generalized cyanosis. His temperature was 99.8 F., pulse rate 150, respiration rate 40 and blood pressure 90/50. Aside from a small bruise on the vertex of his head, the remainder of the physical examination was entirely noncontributory.

Laboratory Data.—On admission his hemoglobin was 13 Gm., erythrocyte count 4,000,000, leukocyte count 50,000 with 90 per cent polymorphonuclear cells and 10 per cent lymphocytes. Nonprotein nitrogen concentration was 44 mg. per 100 cc., fasting blood sugar 254 mg. per 100 cc. (intravenous feeding was in progress at the time). Urinalysis revealed no abnormality. A lumbar puncture showed the spinal fluid to be clear with no cells and with a protein content of 27 mg. per 100 cc. The dynamics were normal.

Hospital Course.—The blood of this patient was also noted to be chocolate brown and did not change when it was equilibrated with air. A clinical diagnosis of methemoglobinemia was made, and he was given 100 mg. of methylene blue intravenously. Blood drawn before the admission of methylene blue showed 78 per cent concentration of methemoglobin. Twenty minutes after the administration of methylene blue the patient was able to speak coherently and at this time gave the above history. In 30 minutes the cyanosis had markedly lessened. His blood pressure rose to 120/80, and two hours after the first injection of methylene blue his methemoglobin was 18 per cent. He was given another 100 mg. of methylene blue and he continued to improve. He was discharged on May 18. This case was complicated at first by the suggestion that the patient's condition might have been due to a head injury he had sustained in the course of his work on the day before admission.

After the discovery that the only etiological factor in common between the first and the second patient was the wheatcakes, butter and syrup which each had eaten at the same restaurant, samples of these materials were collected and investigated by the department of pharmacology. Three cubic centimeters of an aqueous extract of the wheatcakes, syrup and butter was fed to each of three adult male rats by stomach tube. All the animals died in about 35 minutes with quantitative conversion of their hemoglobin to methemoglobin. A qualitative test of this extract was strongly positive for nitrite ion. The department of health was then notified, and samples of all materials which might possibly have been involved in the meal were sent to the department of pharmacology for acute toxicity studies. The pancake batter and the butter were nontoxic, but what was thought to be maple syrup produced methemoglobinemia in rats. It was then learned that the diner prepared its maple syrup by adding maple flavoring extract to sugar syrup. However, when each of these ingredients was tested separately in animals, neither produced methemoglobinemia. On further questioning of the restaurant proprietor, it became apparent that a gallon jug of corning extract, used in corning beef and freshening hamburgers, had been substituted inadvertently for a gallon jug of maple syrup. The corning extract contained large amounts of sodium nitrite and some sugar and appeared grossly like the maple syrup and bore a remarkable resemblance to it in taste.[3]

All hospitals in Syracuse were then notified, and physicians were contacted with regard to any patients with unexplained cyanosis who had appeared within the previous week. In retrospect, the following five patients were given diagnoses of probable methemoglobinemia. None of them had laboratory confirmation of this diagnosis.

CASE 3.—L. B., a 52 year old laborer, had pancakes and syrup on May 11, 1950, at 8:00 a. m. at the diner mentioned above. About one hour later, he appeared dizzy and faint and his fellow workers noticed a bluish tint to his skin and lips. He noticed no dyspnea. He was unable to see a physician that day but left his job during the morning, went home, drank some milk and went to sleep. At 2:30 p. m. he awoke feeling better and walked about. He felt slightly weak for about a week but did not return to work for 12 days. Eleven days after this incident, he received a physical examination which revealed no abnormality.

[2] Evelyn, K. A., and Malloy, H. T.: Micro-Determination of Oxyhemoglobin, Methemoglobin and Sulfhemoglobin in a Single Sample of Blood, J. Biol. Chem. **126**: 655-662 (Dec.) 1938.

[3] This corning extract is known as Afral and contains 8 per cent nitrites, 4 per cent nitrates and sucrose.

Case 4.—M. S., a 38 year old male newspaper employee, was admitted to St. Joseph's Hospital in Syracuse at 4:00 a. m. on May 15, 1950. At 2:00 a. m. on the same morning he had pancakes and syrup at the same diner. He noticed that the syrup tasted salty. One hour later he began to feel weak and his fellow employees noticed his bluish color. At the hospital he was placed in an oxygen tent, with slight improvement, but no other symptoms developed nor were there any positive physical findings. By noon his color was normal and he felt completely well except for some headache. He was discharged at 2:00 p. m.

Case 5.—R. B., a 46 year old white male cabinetmaker, on May 13, 1950, at 9:00 a. m. had pancakes and syrup at the previously mentioned diner. He noticed that the syrup tasted salty. At 10:00 a. m. he began to notice pain in his chest over the region of the heart and epigastric and arm pain, accompanied with palpitation and dyspnea. He was seen by a physician at 1:00 p. m., who noticed extreme cyanosis, dyspnea, auricular fibrillation and a blood pressure of 100/60, although it had previously been 130/80. The patient improved gradually; auricular fibrillation stopped in 24 to 36 hours; cyanosis cleared in 3 to 4 days, and the blood pressure returned to its former level. On May 16, he had some abdominal pain and diarrhea which cleared within 24 hours. An electrocardiogram taken eight days after the acute episode, was normal. The provisional diagnosis on May 13 was coronary occlusion, but the diagnosis in retrospect was methemoglobinemia with coronary insufficiency due to anoxia.

Case 6.—H. H., a 35 year old male newspaper employee, had pancakes and syrup on May 13, 1950, at 7:15 p. m., at the above diner. One hour later he felt nauseated and vomited a small amount of food. He then noticed that his nails were extremely dark. Because of his unsteadiness on his feet, he took a cab home. On arrival home, his wife noticed that he was markedly cyanotic and dyspneic. He went to bed and at 4:00 a. m. felt distinctly better, and his cyanosis had lessened. At 9:00 a. m. he was completely well. He did not see a physician professionally, but reported the episode to a friend who was a physician.

Case 7.—P. T., a 27 year old newspaper employee, had pancakes and syrup with the preceding patient (case 6). He noticed that the pancakes and syrup tasted peculiar and did not finish them. He took two bromo-seltzer® tablets and immediately felt sick but did *not* vomit. On returning to work, his colleagues noticed that he was extremely cyanotic. He noticed only a peculiar taste in his mouth and continued to work for the next 2½ hours; then he went home. The following morning he felt well but retained a peculiar taste in his mouth. He did not consult a physician but reported this incident to the patient mentioned in case 6, who included it in his report to his physician friend.

COMMENT

The clinical diagnosis of methemoglobinemia in case 1 was suggested by (1) the history of sudden onset of cyanosis after eating, (2) the presence of intense cyanosis without gross evidence of cardiac or pulmonary disease, (3) the symptoms and signs of severe anoxia while in an oxygen atmosphere and (4) the peculiar chocolate brown appearance of the blood, with no change in color after oxygen had been bubbled through the sample. In retrospect, typical nitrite hypotensive reactions were observed in cases 1 and 2. The effects of anoxia on the coronary circulation were evidenced in electrocardiographic changes in case 1 and the symptoms of coronary insufficiency in case 5. Presumably, the sickest patients had the greatest nitrite intake; indeed, the first patient even finished the syrup remaining after the wheatcakes had been eaten.

The physiological and pharmacologic mechanisms involved in the appearance and disappearance of methemoglobinemia have been thoroughly reviewed by Finch,[4] whose article presents an excellent discussion. Our patients all had secondary methemoglobinemia, due to accidental nitrite ingestion. Once absorbed, the nitrites oxidized hemoglobin to methemoglobin at a rate faster than the reverse reaction could be carried out by the hypothetical normal cellular mechanisms. There was no evidence that any of these patients suffered a congenital lack of these normal cellular mechanisms (primary methemoglobinemia), and neither ascorbic acid nor glutathione, useful in this congenital type of deficiency[5] was given to these patients. The treatment of secondary methemoglobinemia is based on the observation that methylene blue enormously potentiates the action of the normal red blood cell enzymatic system that reduces formed methemoglobin at a rapid rate.[6] This rate is faster than that at which hemoglobin can be oxidized by most of the known methemoglobin formers.

SUMMARY

As a result of the clinical diagnosis of methemoglobinemia in two patients, the responsible toxin was identified and traced to "maple syrup" served in a public restaurant. Corning extract containing nitrite and sucrose had been inadvertently substituted for the syrup. In retrospect, the diagnosis of methemoglobinemia was made for five additional patients. Methylene blue administered intravenously to the two sickest patients produced dramatic, apparently life saving results.

It is suggested that in view of this episode, suitable steps be taken by public health authorities to identify properly such corning extracts and to call attention to their toxic effects if consumed in quantity.

Preparing Children for Pain.—Virtually all children have a great deal of anxiety about being in hospitals, particularly about the so-called minor operations so common in childhood. Although hospital and operative procedures leave their greatest scars in neurotic children, they also leave some psychic scars in normal children. We have noticed that these are more traumatic to the child when he is not told the truth about the procedure and when it is not discussed with him before it is done. We would like to condemn the common practice of telling a child, "This won't hurt," and then sticking him with a needle, putting an ether mask over his face, etc. It is less traumatic to tell a child that it is going to hurt, but you will try to get it over with quickly and with no more hurting than absolutely necessary, and that he will feel better afterward.—F. G. Ebaugh, M.D., and J. J. O'Hearne, M.D., Psychiatry, in Medicine of the Year: Philadelphia, J. B. Lippincott Company, 1951, p. 71.

HEMOCHROMATOSIS

REPORT OF AN UNUSUAL CASE

Joseph C. Doane, M. D.
Charles H. Kravitz, M.D.
and
Gladys Rosenstein, M.D., Philadelphia

This case of hemochromatosis is reported not only because of the rarity of this condition but also because of some unusual features presented by this patient.

REPORT OF CASE

F. B., a 57 year old white man, was admitted to the Jewish Hospital on April 12, 1949 with a chief complaint of frequency of urination of five weeks' duration. There was no dysuria or hematuria. During the same period the patient experienced a weight loss of approximately 40 pounds (18 Kg.). During the four weeks prior to admission, there was a change of bowel habit from extreme irregularity to persistent constipation necessitating the use of laxatives. In the last two weeks, the patient noted swelling of both feet and legs, extending to the knees. He also noted some postprandial distress, consisting mainly of pain across the upper abdomen. There was no associated nausea or vomiting, polyphagia or polydypsia. There was a history of passing dark brown urine one year ago. The patient had had typhoid at the age of 14 but had not consulted a physician since that time. The family history was noncontributory.

The physical examination revealed a small, thin, emaciated white man, ambulatory and apparently not in acute pain. The skin color was a peculiar slate-gray-bronze, especially over the hands, feet and face; here the skin was dry and desquamating. The scleras were mildly icteric.

The chest was clear. The left border of the heart was at the anterior axillary line. The cardiac rate was 60 per minute, and the blood pressure was 140/70. The rhythm was regular, but a blowing diastolic murmur was heard at the second right costal cartilage.

The abdominal wall presented numerous dilated veins. The abdomen was distended with flank dulness, and a fluid wave was present. The liver was palpable to 10 cm. below the costal margin and was firm and nontender, with a sharp edge. The spleen was not palpable. Ankle edema was extreme.

The laboratory studies on admission elicited the following data: fasting blood sugar, 252 mg. per 100 cc.; blood urea nitrogen, 11 mg. per 100 cc.; icterus index, 15 units; total proteins, 8.5 Gm. per 100 cc., blood chlorides, 510 mg. per 100 cc.; prothrombin time, 15 seconds (50 per cent of normal activity). The urine contained sugar (3 +), no diacetic acid, a slight trace of albumin and acetone (3 +). The blood count showed 12.2 Gm. of hemoglobin per 100 cc., 4,870,000 red cells and 6,400 white cells, of which 45 per cent were polymorphonuclear cells and 55 per cent lymphocytes.

The patient was placed on a diabetic regimen with insulin. There was an extreme lability of the blood sugar, and on several occasions signs of severe hypoglycemia were noted. At one time it was necessary to withdraw insulin completely.

The venous pressure was 13 cm. of water, with a circulation time of 30 seconds from arm to tongue (tested with magnesium sulfate and calcium gluconate) and 27 seconds from arm to lung (tested with ether).

On April 19 a few fine crackles were noted at the base of the right lung, and a chest x-ray showed some evidence of congestive failure.

An electrocardiogram taken at this time was interpreted as showing evidence of myocardial disease but of no recent or remote accident.

The liver function tests showed normal sulfobromophthalein (bromsulphalein®) sodium excretion, thymol turbidity and cephalin flocculation readings. The serum amylase was normal. The blood cholesterol concentration was 181 mg. per 100 cc. of which 40 per cent was cholesterol esters. The prothrombin time continued to range between 35 per cent and 60 per cent of normal values. Two van den Bergh tests showed values of 0.9 mg. and 1 mg. of bilirubin per 100 cc., respectively. Both the acid and the alkaline phosphatase values were normal. The serologic reactions were negative. A gastrointestinal x-ray series revealed only gastritris.

A repeat electrocardiogram on May 5 was interpreted as showing acute damage to the anterior wall of the left ventricle, which had occurred since April 19. A subsequent tracing, on June 2, 1949, was interpreted as showing the typical sequential changes of a recent anterior wall infarction.

A skin biopsy was performed, and the pigmentation was found to be characteristic of hemochromatosis. The urine sediment gave a positive reaction for iron.

The patient's course ran progressively downhill. Under strict diabetic management the skin color became lighter. Terminally, auricular fibrillation developed. Death presumably resulted from heart failure.

Autopsy Observations.—Necropsy was limited to inspection and a microscopic examination of the liver and its adjoining organs.

The liver was hard, extremely nodular and cirrhotic throughout. The surfaces were reddish tan. In the microscopic specimen tan-colored nodules could be seen, surrounded by rings of congestion.

The spleen was only moderately enlarged but was very firm.

The pancreas showed marked fatty infiltration. The remaining very small amount of pancreatic tissue was reddish brown and was congested.

The left kidney was elongated and had a smooth pale surface with congested vessels. The right kidney could not be found.

The intestines were apparently normal, except for a bluish discoloration of the transverse colon.

Histologic Diagnosis.—The histologic diagnoses were hemochromatosis, and severe cirrhosis with extensive deposit of hemosiderin in the liver cells and fibrous tissue.

The causes of death were (1) hemochromatosis, (2) severe hepatic cirrhosis with enormous deposition of iron pigment and (3) atrophy of the pancreas and extensive infiltration with considerable deposit of iron pigment.

COMMENT

This case of hemochromatosis, still a rare disease, presents unusual features. The skin pigmentation was present for many years, but the patient was asymptomatic and quite unaware of any color change. However, once the symptoms of this condition became evident, there was a rapid downhill course. The therapy was most difficult because diametrically opposite indications presented themselves. The liver involvement necessitated use of a high carbohydrate diet, whereas the diabetes demanded some carbohydrate restriction, particularly since stabilization of the blood sugar was an ever increasing problem. During the last several weeks of the patient's illness, he was most apathetic. It was difficult to decide whether the dulled sensorium was due to hepatic toxicity or to cardiac failure. The added myocardial infarction made the picture even more complex. The pathologic changes in the liver no doubt caused the decrease in the prothrombin activity.

SUMMARY

An additional case of hemochromatosis with some unusual features is added to the literature.

A plea is made for an increased awareness of this disease, the triad of symptoms being (1) pigmentation of the skin, (2) hepatic cirrhosis and (3) diabetes mellitus.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized the publication of the following report by the Committee on Pesticides.

R. T. STORMONT, M.D., *Secretary.*

MORE FACTUAL DEATH CERTIFICATES

The Committee has experienced difficulty in preparing useful tabulations on deaths from various poisons because the data furnished by physicians on death certificates have been incomplete. In the past, this was understandable since container labels frequently carried no ingredient statements and the agent responsible for the death often remained unknown. However, with the passage of the Federal Insecticide, Fungicide and Rodenticide Act, economic poisons in interstate commerce are required to carry ingredient statements.

When the name of the active ingredient and the proprietary or trade name of the product suspected of having caused death is not entered on the victim's death certificate, valuable information is omitted. The listing of both the active ingredient and trade name of the suspected product is necessary, since so-called inert ingredients in many preparations may be responsible for death. Common offenders in this category are the solvents frequently used to carry the pesticidal agent. It is equally important that deaths from materials commonly found in the home as well as those associated with agricultural and industrial pursuits be accurately and consistently reported. Only in this way will a balanced picture of relative hazard be obtained.

The preparation of more factual death certificates will facilitate accurate tabulations on the causes of accidental deaths due to poisoning and will ultimately help reduce the loss of lives resulting from the careless use of highly toxic products.

NEW GENERIC AND BRAND NAMES RECOGNIZED BY THE COUNCIL

The Council collaborates with manufacturers in the selection of generic and brand names for marketed drug preparations presented for acceptance and also for new products still under development or clinical trial. The last report on such names appeared in THE JOURNAL, March 3, 1951, p. 644.

The following abstract lists the generic designation, the chemical name, where necessary for information, and the recognized brand name or names under which the preparations are available. In general, a generic name should bear recognizable relation to the chemical name and conform as closely as consistent with brevity and practicality to existing systems of scientific nomenclature. The chief requirement for a brand name is that it should not be therapeutically suggestive.

Choline Gluconate for the gluconate salt of choline, 2-(hydroxyethyl)trimethylammonium D-gluconate

Chlorcyclizine Hydrochloride for 1-*p*-chlorobenzhydryl-4-methylpiperazine hydrochloride: Di-Paralene Hydrochloride (Abbott Laboratories)

Dimethyl-Tubocurarine Chloride: Mecostrin Chloride (E. R. Squibb & Sons)

Ergotamine with Caffeine for ergotamine tartrate and caffeine combined: Cafergot (Sandoz Pharmaceuticals)

Khellin (Instead of Visammin) for 2-methyl-5,8-dimethoxyfuranochromone

Khellol Glucoside for 2-methylol-5-methoxyfuranochromone glucoside

Methyl Hexane Amine for 1,3-dimethylamylamine: Forthane (Eli Lilly & Company)

Phenacemide for phenacetylcarbamide: Phenurone (Abbott Laboratories)

Probenecid for *p*-(di-*n*-propylsulfamyl)benzoic acid: Benemid (Sharp & Dohme, Inc.)

Salicylazosulfapyridine for 4-(pyridyl-2-amidosulfonyl)-3'-carboxy-4'-hydroxyazobenzene

Tetraethylammonium Chloride: Etamon Chloride (Parke, Davis & Company)

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. STORMONT, M.D., *Secretary.*

Aminophylline-U.S.P. (See New and Nonofficial Remedies 1950, p. 278).

Tablets Aminophylline: 0.1 gm. and 0.2 gm. Professional Drug Service, Inc., St. Louis.

Gamma Benzene Hexachloride (See THE JOURNAL, Oct. 14, 1950, p. 548).

Ointment Kwell 1%: 56.7 gm. tubes and 454 gm. jars. An ointment containing 10 mg. of gamma benzene hexachloride in each gram. Commercial Solvents Corporation, New York.

Diethylstilbestrol-U.S.P. (See New and Nonofficial Remedies 1950, p. 331).

Tablets Diethylstilbestrol: 0.1 mg., 0.25 mg., 0.5 mg., 1.0 mg., and 5.0 mg. Barlow-Maney Laboratories, Inc., Cedar Rapids, Ia.

Diphtheria Toxoid, Alum Precipitated-U.S.P. (See New and Nonofficial Remedies 1950, p. 438).

Diphtheria Toxoid (Alum Precipitated): 5 cc. vials (five immunizations). Preserved with thimerosal 1: 10,000. Pitman-Moore Company, Division of Allied Laboratories, Inc., Indianapolis.

Diphtheria Toxoid, Alum Precipitated: 1 cc. (0.5 cc. dose form), 5 cc. (0.5 cc. dose form), and 10 cc. (1 cc. dose form) vials. One immunization, five immunizations, and five immunizations, respectively. Preserved with thimerosal 1: 10,000. E. R. Squibb & Sons, New York.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

HOWARD A. CARTER, *Secretary.*

ACE ELASTIC HOSIERY ACCEPTED

Manufacturer: Becton, Dickinson & Co., Rutherford, N. J.

Ace Elastic Hosiery is designed to give support to varicose and phlebitic veins and to control the swelling of the leg in various circulatory and inflammatory conditions. It is intended to form a smooth sheath over the leg and is described as "full-footed," meaning that the patient does not have to wear a second pair of hose over the elastic stockings. They are knitted of nylon and rubber with cuffs of nylon and mercerized cotton.

Evidence from sources acceptable to the Council indicated that these hose were of good quality, that they were as durable as could be expected in view of the sheerness which many patients desire, and that the results of wearing them were satisfactory provided precautions were taken to secure a proper fit. The Council on Physical Medicine and Rehabilitation voted to include the Ace Elastic Hosiery in its list of accepted devices.

THE VALUE OF TOTAL POPULATION X-RAY SURVEYS

Total population x-ray surveys of the chest have been extensively prosecuted in this country in the campaign against pulmonary tuberculosis. The problems of quality of roentgen reproduction, of reliability of roentgen interpretation, of thoroughness of follow-up, and of reduction of local incidence of tuberculosis have been studied to some extent and has been commented on by various groups to a considerable extent. However, no really comprehensive review of a long term, total population study has yet been made in this country. A recent follow-up report on a total population survey of the island of Gotland, made in 1943 and analyzed in succeeding years by Lonnerblad,[1] is of interest. Gotland was almost an ideal location for a successful total population survey. The island is comparatively remote and has a negligible immigration factor. It is about seven hours by sea from the mainland of Sweden.

In this mass photofluorographic survey, 56,964 persons were examined, which is equivalent to 99% of the population over the age of 1 year. This is a remarkable achievement, as most surveys fail to exceed 80% of the population over the age of 16. The customary small percentage of adults with potentially significant pulmonary shadows and the even smaller percentage of persons with open pulmonary lesions were discovered. The long-term value of the survey, namely, its apparent influence on the prevention of tuberculosis (as a result of the detection and isolation of active cases), was studied by observation of the tuberculosis mortality in Gotland for the ensuing seven years and comparison with the mortality for Sweden as a whole (which had not yet undertaken extensive total population surveys). The mortality rate for tuberculosis per 100 inhabitants in Gotland in 1946 was 0.54 and for Sweden as a whole 0.51. For 1947, the respective figures were 0.49 and 0.48, and for 1948, 0.70 and 0.48. Therefore, there was no appreciable reduction in mortality and apparently little improvement in prevention of tuberculosis. Even three years after completion of the survey, it was noted that more than half of the newly discovered cases of open pulmonary tuberculosis had already passed the moderate stage.

Lonnerblad points out that it is not feasible at the present time to isolate effectively all persons with intermittently open pulmonary tuberculosis. Further, in some persons with lesions that are radiographically improving, rapid progression or reactivation even of apparently stable foci may suddenly develop. These persons, clinically well for a period of years, have ample time to infect a considerable number of other persons before being detected. Two or three such cases in a populous community will entirely neutralize the value of a periodic mass survey.

Even in a homogeneous, relatively isolated area like Gotland, it proved very difficult to trace sources of infection or to trace and examine a majority of contacts of open cases. However, even if such were possible, the small number of coexisting "carriers" of tubercle bacilli (with minimal or negligible pulmonary roentgen shadows) tend to vitiate the program. Some careful persons with open tuberculosis may not act as carriers, but others, especially those in whom there develops undetected, rapidly progressive tuberculosis, may in a short time be a source of infection to large numbers of persons. A man may have been assured that his last photofluorogram was normal, and it does not occur to him that he may be a victim of open disease.

The author suggests that the promotion of some means of general prophylaxis of the total population (such as by BCG vaccination), as well as the promotion of improved general economic conditions, is essential before total population surveys can produce the desired results. At the same time, it is observed that mass surveys of selected groups, such as persons segregated in institutions or otherwise thrown in close contact, have an obvious constructive place in preventive medicine, provided it is borne in mind that negative results merely exclude evidence of disease at that particular moment.

SURGICAL RELIEF OF PULMONIC STENOSIS IN TETRALOGY OF FALLOT

Early attempts at surgical relief of stenotic valvular lesions of the pulmonary artery and the heart were disappointing and led to justified pessimism as to the feasibility of surgical therapy. Recent advances in intrathoracic surgery, in the art of anesthesia, in preoperative and postoperative treatment, in blood transfusion and employment of oxygen, all served to revive interest in the surgical attack on congenital anomalies of the heart. The almost hopeless prognosis of the morbus caeruleus made it apparent that the risk of operation was probably less than that of leaving the condition untreated.

Blalock and Taussig [1] in 1945 introduced an operative procedure for the relief of pulmonic stenosis. The operation consisted of anastomosing one of the systemic arteries, preferably the subclavian, to one of the pulmonary arteries. This shunting operation created an artificial ductus arteriosus and increased the flow of oxygenated blood through the lungs, thereby reducing cyanosis. Blalock was able to report in 1948 on 610 patients subjected to the operation for the relief of pulmonic stenosis, with a mortality rate of 17.7 per cent. The results were gratifying, particularly with regard to the lessening of the patient's incapacity.

[1] Blalock, A., and Taussig, H. B.: The Surgical Treatment of Malformations of the Heart in Which There Is Pulmonary Stenosis or Pulmonary Atresia, J. A. M. A. **128**: 189 (May 19) 1945.

The important lesion in the tetralogy of Fallot is the pulmonary stenosis. Two types of stenosis exist: valvular and infundibular, in which there is a formation of a ridge of tissue just below the valves. This ridge or septum encroaches on the lumen of the artery and contributes to the formation of a sort of fifth cardiac chamber. In either instance the pulmonary artery may be normal in size, hypoplastic or dilated. Either lesion interferes with the free flow of blood into the pulmonary circulation. Potts and co-workers [2] introduced a modification of the Blalock operation, anastomosing the pulmonary artery and the aorta. The advantages of this procedure are to be seen in cases in which the subclavian artery is too small or too short. The disadvantage of the Blalock procedure is the creation of a ductus arteriosus with possible later development of subacute bacterial endocarditis. There is also some question as to whether the anastomosis will keep pace with the growth of the patient.

Accurate diagnosis of the existing congenital anomaly can be achieved in most instances with the aid of arteriography and intracardiac catheterization. Brock [3] attempted direct inspection of the valves of the pulmonary artery in the course of the operation by introducing a cardioscope into the left pulmonary artery. The maneuver, however, was not always feasible and was frequently too hazardous. On the other hand, palpation of the exposed pulmonary artery and the right ventricle, Brock points out, reveals in a case of valvular pulmonary stenosis a well localized thrill. The thrill can be felt to be localized within the central portion of the lumen. In subvalvular or infundibular stenosis, no such characteristically localized thrill is felt in the first part of the pulmonary artery. Brock has reintroduced Doyen's unsuccessful attempt at a direct attack on the stenotic tissue. In the Brock procedure a valvulotome is passed through the wall of the right ventricle upward into the pulmonary artery. His first report dealt with three patients: one died; embolism of the lower extremity developed in one and hemiplegia in the third. These vascular complications were probably due to the fall in the blood pressure in the presence of polycythemia. Relief of infundibular stenosis is a far more complicated procedure, since it involves resection of a portion of the actual wall of the active ventricular muscle and not a simple division of a narrowed valve at the exit of the ventricle. Brock [4] accomplished this with a special instrument, a type of rongeur, which is introduced into the right ventricle and is passed upward in the direction of the pulmonary artery. The stenotic tissue is bitten off, the instrument is removed and the opening is further dilated with a special instrument. Blalock [5] reported a series of 19 cases of Brock valvulotomy for pure pulmonary stenosis with excellent results.

Downing and his associates [6] performed the Brock procedure in eight cases of tetralogy of Fallot. In six of these the improvement in exercise tolerance has been striking. These authors consider Brock's procedure the operation of choice in cases of pulmonary stenosis. There are, however, a number of questions that have not so far been answered, pertaining to (1) the incidence and effect of pulmonary regurgitation in cases in which the stenosed valve is divided, (2) the possibility of later development of subacute bacterial endocarditis and (3) the possibility that the valves might again fuse at some time or that the outflow tract might again become obstructed in cases in which infundibular stenosis has been corrected.

The results thus far achieved by both the indirect and the direct attack on the congenital anomaly known as the tetralogy of Fallot justifies the conclusion that an enormous advance has been made in the treatment of the hitherto hopeless case of the blue baby. The methods evolved will probably receive further refinement and will find application in acquired valvular disease of the adult as well.

MICROBIAL METABOLITES AND PLANT WELFARE

The dramatic advances of the past 10 years in the medical use of antibiotics have overshadowed the potential role of those substances in other fields. The use of antibiotics with antifungal properties for the control of plant diseases is of particular interest at a time when conservation of food supply is a matter of world-wide importance. Two recent reports are of considerable theoretical interest in that they suggest means by which the value of antibiotics in agriculture and horticulture can be further explored.

Henry [1] and his associates recently reported on the control of seed-borne fungus disease in cereals with acidione, an antibiotic produced by Streptomyces griseus. Wheat, barley, and oat seeds infested with covered smut were treated with acidione in a concentration of 10 parts per million in water. Treatment resulted in a reduced incidence of disease in all cases. Best results were obtained with oat smut, a major disease, and one of the covered smuts most difficult to control successfully by seed treatment. Acidione proved to be as effective as mercurials and formaldehyde and appeared to have no serious toxic action on the seed.

Brian, Wright, Stubbs, and Way [2] have reported that resistance to fungal parasites may be conferred on plants by antibiotic substances taken in through the root system and translocated to the leaves. For their studies, they used a fungistatic antibiotic, griseofulvin, which is produced by a common soil organism and which is relatively nontoxic to higher plants. They found that, if lettuce or oat seedlings were grown in nutrient solutions containing griseofulvin, the antibiotic could, after a period of time, be demonstrated in the leaves or in guttation-drops. Furthermore, when disease-causing fungus spores were sprayed onto lettuce or tomato plants that had been growing in griseofulvin-containing solutions for several days, the disease developed much more slowly than in control plants. More crucial experiments to prove whether griseofulvin could be produced by microbiologic synthesis in the soil and then pass into plants were inconclusive. The demonstration of such an effect would serve to indicate that the rhizosphere, or zone of increased microbial activity in the soil adjacent in plant roots, may make an important contribution to the welfare of the plant.

MUSCLE RELAXANTS IN LOW-BACK DISORDERS

Schlesinger and Stinchfield [1] have reported on the use of the muscle relaxant mephenesin as a diagnostic and prognostic aid in acute disorders of the lower back. They administered the drug intravenously to 64 hospitalized patients with acute symptoms and signs of herniated intervertebral disk and observed its effect on the pain and on the results of the straight-leg-raising test. Four types of reaction were noted: (1) abrupt relief of low-back and sciatic pain and striking increase in the range of leg motion, (2) abrupt relief of pain with only slight or moderate increase in range of leg motion, (3) abrupt relief of pain with no increase in motion, and (4) rapid relief of local pain, paradoxical aggravation of radiating pain and decrease or no change in straight-leg-raising ability. Patients with the first type of reaction often obtained persistent relief from this test administration of mephenesin, and a high percentage left the hospital symptomatically well after a period of conservative treatment. These patients, some of whom showed unequivocal myelographic evidence of herniated intervertebral disk, were regarded as having reversible nerve root compression, possibly aggravated by reflex muscle spasm. Patients with the third or fourth type of reaction to mephenesin invariably failed to respond to subsequent conservative treatment, and all required surgical intervention within three months. At operation in each case, there was found a large protrusion of the intervertebral disk producing irreducible root compression. Patients with the second type of reaction to mephenesin formed an intermediate group; some required surgical treatment, and others responded to conservative management. Thus in all but the second group the mephenesin test had definite prognostic value at least as far as the response of the immediate attack to therapy was concerned. This is of considerable practical significance in a condition in which the choice between conservative and surgical treatment is often difficult. An accurate prognosis can spare many patients the economic burden of long periods of useless conservative therapy while assuring others, who are likely to benefit from it, of an adequate trial of nonsurgical therapy.

Whether this test will prove more helpful in this respect than the procaine hydrochloride test of Steindler [2] can be determined only by further clinical trial. It already appears that mephenesin is superior to procaine in the relief of local muscle spasm. Because in large doses, it can produce paralysis, however, mephenesin must be given cautiously and only to hospitalized patients who do not show muscular weakness or serious neurologic disturbance. In these experiments a 2% solution administered intravenously produced no hemoglobinuria or other serious side effects. Given orally, the drug proved unsatisfactory in the hands of these investigators.

The muscle relaxation produced by mephenesin has also been found helpful as an adjunct to traction and in the relief of pain in various low-back syndromes, by the above-mentioned authors and by others,[3] but it appears likely that the drug will have its greatest usefulness in differential diagnosis and prognosis.

RELATIONSHIP BETWEEN EPIDEMIC KERATOCONJUNCTIVITIS AND THE NERVOUS SYSTEM

Ruchman [1] has recently shed interesting and additional light on the nature of the epidemic keratoconjunctivitis (EK) virus. This work, confirmed by Cheever,[2] suggests the possibility that the virus of epidemic keratoconjunctivitis, originally isolated by Sanders,[3] has a biphasic pathogenicity referable to ocular and nervous tissues. The recent findings indicate a close immunologic relationship between the viruses of epidemic keratoconjunctivitis and St. Louis encephalitis; indeed, the two agents could not be differentiated by intracerebral neutralization tests. A similar relationship, but to a lesser degree, was demonstrated between epidemic keratoconjunctivitis and Japanese and West Nile encephalitis viruses. The only demonstrable difference between epidemic keratoconjunctivitis and St. Louis viruses was to be found in the increased pathogenicity of the epidemic keratoconjunctivitis virus for rabbits. These findings are consistent with those of Sanders, who reported passage of his original virus through graded collodion membranes with an average pore diameter of 75 to 100 mμ, while those membranes with an average pore diameter of less than 50 mμ retained the virus.

During the 1942 epidemics, which involved thousands of industrial workers in California and New York, a severe ocular disease was observed in as high as 10% of factory personnel. Even at that time, severe headaches associated with the conjunctivitis and unrelieved by analgesics were observed by the University of Miami investigator. Furthermore, two cases in Schenectady showed possible central nervous system involvement.[4]

C.: Epidemic Keratoconjunctivitis: Isolation and Identificiation of Filterable Virus, J. Exper. Med. **77:** 71-96 (Jan.) 1943. Sanders, M.; Gulliver, F. D.; Forchheimer, L. L., and Alexander, R. C.: Epidemic Keratoconjunctivitis: Clinical and Experimental Study of Outbreak in New York City; Further Observations on Specific Relationship Between a Virus and the Disease, J. A. M. A. **121:** 250-255 (Jan. 23) 1943.

The present clarification of this problem throws an important light on virus diseases with respect to potential multiple variants within a single disease agent. In the case of epidemic keratoconjunctivitis, we are apparently dealing with an agent capable of great ocular infectivity, potentially neurotropic in character. The relationship between epidemic keratoconjunctivitis and the neurotropic virus is closely paralleled in the herpes simplex virus, insofar as the herpes virus is capable of infecting the eyes of humans and then quickly reverting to a strongly neurotropic agent by passage in laboratory animals. However, in the case of the herpes virus, the agent is approximately 125 mμ, and neutralizing antibodies are found in as high as 75% of unselected adult serums.[5] Epidemic keratoconjunctivitis, on the other hand, has a calculated measurement of approximately 35 mμ, and neutralizing antibodies against it are not found in a so-called normal population.[6]

ALCOHOL IN PULMONARY EDEMA

The usefulness of ethyl alcohol in the treatment of paroxysmal pulmonary edema in rabbits and dogs has recently been demonstrated by Luisada.[1] Working on the theory that the respiratory obstruction occurring in pulmonary edema is due chiefly to the foaming of the fluid present rather than to its volume per se, this investigator tested the effects of a number of antifoaming agents administered by inhalation to animals with experimental pulmonary edema. Of the agents used, 95% alcohol in subanesthetic doses produced the most satisfactory results. It doubled the survival time of rabbits with pulmonary edema produced by intravenously administered epinephrine and completely prevented pulmonary edema in dogs subjected to rapid intracarotid infusion with isotonic sodium chloride solution. This effect was thought to be due to the local antifoaming action of alcohol, but it was subsequently observed that larger, mildly anesthetic doses of 50% alcohol given by gavage or enema had a similar action. Subanesthetic doses of 25% alcohol administered intravenously also showed definite, but less pronounced, therapeutic effect. These observations suggest that the depressant action of alcohol on the central nervous system also played a therapeutic role. It is possible that both factors were active, since alcohol in the blood stream may be excreted through the lungs, exerting a local effect, while inhaled alcohol may be absorbed into the blood stream, with consequent central action.

In similar experiments, it was found that the combination of alcohol by inhalation and morphine by injection produced better results than either one alone and that these results were equivalent to those obtained with morphine plus inhalations of oxygen under pressure. This led Luisada to suggest that the combination of morphine, alcohol vapor, and oxygen under pressure might prove most effective in the treatment of pulmonary edema. Therapeutic trials with alcohol inhalations in man are now in progress.

IRRADIATED TUBERCULOSIS VACCINE

Milzer[1] and associates of Michael Reese Hospital, Chicago, report evidence that ultraviolet-killed tuberculosis vaccine is superior to BCG vaccine as a prophylactic agent. Mycobacterium tuberculosis (hominis) grown for 14 days on Petragnani medium was harvested, weighed, suspended in sterile distilled water, ground for 30 minutes in a ball mill, and then diluted so as to contain 1 mg. of moist bacilli per cubic centimeter. Exposure for 0.5 seconds to ultraviolet irradiation was found sufficient to kill the bacteria, after which 1:10,000 thimerosal was added as a preservative and the killed vaccine was stored in the refrigerator at 3 to 5 C. Freshly prepared viable BCG vaccine was used in comparison.

Comparative active immunization tests were made on groups of 24 to 40 mice. At weekly intervals, each mouse was given four subcutaneous injections of 0.5 mg. of the selected vaccine. Thirty days after the fourth dose, each mouse was given a challenging dose of 0.001 to 0.025 mg. of the 14-day-old slant cultures of H37Rv tubercle bacilli suspended in 2.5% gastric mucin. Half of the challenging dose was given subcutaneously and half intraperitoneally. Control tests were made on nonimmunized mice. All animals were killed 30 days after the challenge dose and examined carefully for lesions.

Without exception, all control mice presented gross lesions, ranging in size from 2 to 4 mm., at the site of the inoculation, or in the liver, spleen, or peritoneum. Gross lesions developed in only 53% of the mice given the viable BCG vaccine and in only 37.5% of those given the nonviable irradiated vaccine. The irradiated vaccine thus appeared to afford better protection than the BCG vaccine against subsequent tuberculosis.

This superiority was not evident, however, in similar experiments performed by Olson[2] and Sarber[3] on guinea pigs. Using larger challenging doses of virulent bacilli and longer periods of observation, they found that the protection afforded by the two types of vaccine was about equal. That the protection was not complete is indicated by the observation that 32% to 55% of the vaccinated animals died within four months after infection. This was in contrast to a mortality rate of 71% in the unvaccinated animals.

Aside from the question of its relative antigenicity, however, the irradiated vaccine has other advantages over BCG. Unlike viable BCG, it contains a preservative that prevents contamination with pathogens; also, it is remarkably stable, retaining its potency for as long as 12 months after its preparation.

ORGANIZATION SECTION

COMMITTEE ON CONSTITUTION AND BY-LAWS

The permanent Committee on Constitution and By-Laws of the American Medical Association held its organizational meeting during the annual session at Atlantic City. Dr. Louis A. Buie of Rochester, Minn., is Chairman. The other members of the Committee are Dr. Stanley H. Osborn, Hartford, Conn.; Dr. Britton E. Pickett Sr., Carrizo Springs, Texas; Dr. James S. Stevenson, Tulsa, Okla.; Dr. Floyd S. Winslow, Rochester, N. Y.; the President, Dr. John W. Cline; the Secretary, Dr. George F. Lull; the Assistant Secretary, Dr. Ernest B. Howard; the representative of the Board of Trustees, Dr. Edwin S. Hamilton; the Speaker of the House of Delegates, Dr. F. F. Borzell, and the Vice Speaker, Dr. James R. Reuling. Drs. Cline, Lull, Howard, Hamilton, Borzell, and Reuling are ex officio members of the Committee, without the right to vote.

Any member of the Association who has suggestions for amendments to the Constitution and By-Laws should send them to Dr. Buie, whose address is 102 Second Ave., S. W., Rochester, Minn. The Committee will make a report to the House of Delegates at the Clinical Session in Los Angeles in December.

FEDERAL LEGISLATION

Income Tax Deductions for Medical Expenses

Representative Clemente of New York introduced H. R. 4405, to allow medical and dental expenses as deductions from gross income for income tax purposes. The provisions of the present tax law permit a taxpayer, in arriving at taxable income, to deduct medical and dental expenses in excess of 5% of adjusted gross income, with a limitation on the total amount deductible. This bill proposes to permit a taxpayer to deduct all expenses paid during the taxable year, not compensated for by insurance or otherwise, for medical care of the taxpayer, his spouse, or other legal dependents. The term "medical care" is defined in its broadest sense to include diagnosis, cure, mitigation, treatment, and prevention of disease. Included also as deductible items would be amounts paid for health or accident insurance. The author introduced a similar but not identical bill in the 81st Congress.

STATE LEGISLATION

Alabama

Bills Introduced.—H. 444, proposes regulations requiring every dog owner to cause his dog to be inoculated against **rabies** by the rabies inspector once each year. S. 3401, proposes the creation of a **State Board of Chiropractic Examiners** and proposes that a person shall be regarded as practicing chiropractic who shall employ objective or subjective means without the use of drugs, surgery, X-ray therapy or radium therapy, for the purpose of ascertaining the alignment of the vertebrae of the human spine, and the practice of adjusting the vertebrae to correct any subluxation or malalignment thereof.

California

Bills Introduced.—A. 3456, to amend that the Health and Safety Code, proposes to make it a felony to sell, furnish, administer, give or offer to sell, furnish, administer or give any **narcotic to a minor.** S. R. 187, proposes the creation of an Interim Committee on **Narcotics and Hypnotics** to ascertain, study and analyze all facts relating to narcotics and hypnotics including the operation, effect, administration, enforcement and needed revision of all laws relating thereto. S. 1542, proposes to amend the initiative act relating to **chiropractic** by authorizing the Board of Chiropractic Examiners to issue a certificate authorizing the holder thereof to practice chiropractic and other forms of therapy as taught in chiropractic schools or colleges.

Florida

Bills Enacted.—H. 1440 became Law Without Approval June 11, 1951. It provides for the creation of a special **hospital district** for Broward County. S. 254 was approved June 4, 1951. It provides for the establishment and operation of a State Hospital for **alcoholism.** S. 325 was approved May 28, 1951. It amends the law prohibiting **trafficking** in the **dead body of a human being** and provides that nothing in such law should be construed to prohibit the obtaining, dissecting, using and disposing of dead bodies for the purpose of teaching or other appropriate university research by any medical school, dental school, school of nursing or other university research or teaching unit which is a part of a regularly established or chartered institution of higher learning under the Laws of the State.

Illinois

Bills Introduced.—S. 275, to amend the Workmen's Compensation Law, proposes to authorize the payment of compensation for loss of the **industrial use** of one or both **ears.** S. 773, proposes the creation of a Commission on **Tuberculosis** Problems to study all matters pertaining to intergovernmental and other cooperation in the control and eradication of tuberculosis. S. 755, to amend the Medical Practice Act, proposes regulations for the issuance of **Temporary Certificates of Registration** to persons who are nonresidents of the State, who have a Doctor of Medicine degree, and who wish to pursue programs of graduate or specialty training in the State.

Bill Enacted.—H. 163 was approved June 14, 1951. It repeals and re-enacts the law relating to the practice of **nursing.**

Michigan

Bills Enacted.—H. 319 has become Public Act No. 249 of the Acts of 1951. It amends the Michigan **Hospital Survey and Construction** Act by increasing the number of members of the Advisory Hospital Council from 11 to 12 and by specifying that one member of such council shall be appointed from a list of full time help officers submitted by the Board of Directors of the Michigan Health Officers Association. S. 152 has become Public Act No. 231 of the Acts of 1951. It proposes certain amendments to the law providing for the licensing of **maternity or lying-in hospitals.**

Missouri

Bill Introduced.—H. 275, proposes certain amendments to the law regulating the sale of **narcotic drugs** by, among other things, providing for the establishment of a Narcotic Drug Act Fund, into which shall be placed all fees collected for narcotic licenses and out of which shall be paid the expenses incurred by the division of health in the administration of the law regulating narcotic drugs.

Ohio

Bill Enacted.—H. 516 was approved June 18, 1951. It provides for the issuance of **special automobile licenses** bearing the word "physician" to persons holding unrevoked and unexpired licenses to practice medicine in the State.

Wisconsin

Bills Enacted.—A. 473 has become Chapter 369 of the Laws of 1951. It amends the **basic science act** by exempting therefrom dental hygienists. A. 616 has become Chapter 368 of the Laws of 1951. It amends the medical practice act by eliminating reference to **osteopathy** and surgery and by providing that if six members of the board find an applicant qualified, the board shall issue a license to practice medicine and surgery to such applicant. S. 701 has become Chapter 371 of the Laws of 1951. It amends the medical practice act by authorizing the board of medical examiners and the board of chiropractic examiners to make use of the **injunctive process** to restrain violations of the law.

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE ANNUAL SESSION IN ATLANTIC CITY, N. J., JUNE 11-15, 1951

(Concluded from page 854)

Resolution on Establishment of Single Membership Classification

Dr. George Earl, Minnesota, submitted the following resolution, which was referred finally to the Reference Committee on Amendments to Constitution and By-Laws:

WHEREAS, The new system of American Medical Association membership would appear to make the classification of "Fellow" an outmoded and unnecessary one; and

WHEREAS, Many active members of the American Medical Association feel that no purpose is served by requiring the payment of an extra $5 for the privilege of program participation, serving in the House of Delegates or as an official of the American Medical Association; and

WHEREAS, The present membership stratum is inconsistent with the democratic foundation and objectives of the American Medical Association; therefore be it

Resolved, That the American Medical Association establish a single member classification, providing all active members with equal rights and privileges.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS

Dr. Robertson Ward, Chairman, submitted the following report, which was duly adopted:

To your reference committee were referred three resolutions having to do with single membership in the American Medical Association, involving the abandonment of Fellowship. These were introduced by Dr. Woodhouse of Ohio, Dr. McKittrick of Massachusetts and Dr. Earl of Minnesota. A very thorough discussion was held on the pros and cons, with the following result: That your reference committee approves the principle involved in these resolutions, especially as to eligibility of members to take part in organizational and scientific programs of the American Medical Association without the necessity of other than regular membership. Since there is a definite question of the advisability of abandoning the term "Fellowship," it is the recommendation of your committee that this matter be referred to the standing committee of the House on Constitution and By-Laws, with instructions to prepare such changes in the Constitution and By-Laws, in consultation with the Board of Trustees, as may be necessary to carry out these recommendations, and with instructions to present these necessary changes to the House of Delegates at its next meeting.

Resolution on Standardized Form for Reporting Health and Accident Cases

Dr. George Earl, Minnesota, submitted the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Reporting health and accident cases to insurance companies could be simplified and expedited by one standard form, adopted by all insurance companies concerned with this form of coverage; and

WHEREAS, The advantages of a single form would also increase the efficacy of procedures under the Workmen's Compensation Law; therefore be it

Resolved, That the problem of eliminating diversity of insurance reporting forms be referred to the proper committee of the American Medical Association, with instructions to create a standardized form for reporting health and accident cases.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

In view of the various state laws, it would be difficult and physically impossible to have a standardized form that would comply with the laws of the 48 states. Your reference committee recommends that this matter be handled on an individual state level. Therefore, the reference committee disapproves this resolution.

Resolution on Payment of American Medical Association Dues

Dr. George Earl, Minnesota, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, There has been misunderstanding regarding the transition of the $25 payment to the American Medical Association, from the category of "special assessment" to "annual dues"; and

WHEREAS, Many physicians who did not remit their 1950 dues and who now wish to become members and pay their 1951 dues, have been classified as delinquent members and can no longer be members of the American Medical Association until their 1950 dues have been paid; and

WHEREAS, Many physicians were aware that the special assessment in 1949 was not considered legally binding and, therefore, considered the same to hold true of the 1950 payment; therefore be it

Resolved, That the American Medical Association reconsider its decision of December 1949 and accept payment of 1951 dues, regardless of the payment or nonpayment of 1950 dues.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report, which was duly adopted:

Your reference committee recommends disapproval of this resolution.

Resolutions on Publicizing American Medicine

Dr. Edward P. Flood, New York, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The American Medical Association wisely expended large sums of money to conduct its recent National Education Campaign; and

WHEREAS, Failure to follow up this campaign by repeated presentation of the true story of American medicine to the public may cost much of the advantage gained; and

WHEREAS, Most physicians make substantial contributions annually to educational, welfare, religious and eleemosynary groups and this follow-up may be accomplished by purchasing advertising space in their journals, annuals and programs; and

WHEREAS, The Principles of Medical Ethics rightfully precludes the use of this space for advertising the individual physician; therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby endorses the use of such advertising space for slogans which would advance the cause of American medicine; and be it further

Resolved, That the Public Relations Bureau of the American Medical Association is hereby directed to draft a number of appropriate slogans for use by the members of the American Medical Association; and be it further

Resolved, That said slogans be published in The Journal of the American Medical Association with appropriate comment.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, presented the following report, which was duly adopted:

The resolutions introduced by Dr. Edward Flood of New York have been amended as follows:

WHEREAS, The American Medical Association wisely expended large sums of money to conduct its recent National Education Campaign; and

WHEREAS, Failure to follow up this campaign by repeated presentation of the true story of American medicine to the public may cost much of the advantage gained; and

WHEREAS, Most physicians make substantial contributions annually to educational, welfare, religious and eleemosynary groups and this follow-up may be accomplished by purchasing advertising space in their journals, annuals and programs; and

WHEREAS, The Principles of Medical Ethics rightfully precludes the use of this space for advertising the individual physicians, but does not preclude the use of such space for such short slogans as would advance the cause of American medicine; therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby endorses the use of such advertising space for slogans; and be it further

Resolved, That the Public Relations Department of the American Medical Association is hereby directed to draft a number of appropriate slogans for use by the members of the American Medical Association for this purpose.

Your Committee approves this resolution as amended, and recommends its adoption.

Resolutions on Emergency Medical Call Service

Dr. Harold F. R. Brown, New York, presented the following resolutions, which were referred to the Reference Committee on Insurance and Medical Service:

Whereas, An emergency medical call service is of proven value both as a community public service and a means of good public relations between a physician and his community; and

Whereas, Participation in such a service is not onerous if many physicians cooperate; and

Whereas, Every county medical society has been asked to operate such an emergency service; therefore be it

Resolved, That every doctor below the age of 35 years, regardless of his type of practice, be urged to participate in his community's emergency call plans; and be it further

Resolved, That all national specialty boards be requested by the Secretary of the American Medical Association to facilitate such general participation by assuring their members and potential members that they may participate in such a community activity without jeopardy to specialty ratings.

Report of Reference Committee on Insurance and Medical Service

Dr. William R. Brooksher, Chairman, presented the following report, which was duly adopted:

Your committee recommends approval of these resolutions with the provision that they be amended to read that all national specialty boards be requested by the American Medical Association to facilitate such general participation by assuring their members and potential members that they may participate in such a community activity without jeopardy to specialty ratings.

Resolution on Communism

Dr. L. A. Alesen, California, submitted the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The American Medical Association and its constituent state and component county societies have taken the lead in a nationwide fight to regain and preserve for Americans their birthright of individual freedom; and

Whereas, In a time of clear and present danger, there is no place for neutrality; therefore be it

Resolved, That the American Medical Association hereby expresses its supreme contempt for and its unalterable opposition to communism, nazism, fascism, state socialism, or any other form of collectivism, because these philosophies and the social and economic orders representing them violate nature's fundamental age-old principle of individual responsibility and therefore can never produce anything but human poverty, misery and ultimate moral and spiritual disintegration.

Report of Reference Committee on Miscellaneous Business

Dr. Andrew A. Eggston, Chairman, submitted the following report, which was adopted unanimously:

Resolution on Communism: Your Reference Committee wishes to offer the present substitute motion which amounts to a rewording of the original resolution:

Whereas, The American Medical Association and its constituent state and component county societies have taken the lead in a nationwide fight to regain and preserve for Americans their birthright of individual freedom; therefore be it

Resolved, That the American Medical Association hereby expresses its unalterable opposition to communism, nazism, fascism, state socialism or any other form of collectivism, because these philosophies and the social and economic orders representing them violate the principles on which this country was founded.

Your Reference Committee recommends approval of this substitute resolution.

Proposed Amendment to By-Laws, Chapter IX, Section 1 (B)

Dr. J. P. Wall, Mississippi, presented the following proposed amendment to Chapter IX, Section 1(B), which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

Amend Chapter IX, Section 1 (B) by adding to the first paragraph the following sentence:

"Past Presidents of the American Medical Association shall serve for a period of five years immediately following their tenure of the presidency of the American Medical Association."

So amended, the first paragraph of Section 1 (B) of Chapter IX of the By-Laws would read as follows:

Term—Delegates and alternates from constituent associations, sections, the United States Army, the United States Navy, the United States Air Force, the United States Public Health Service and the Veterans Administration shall be elected or appointed, as the case may be, for two year terms and shall assume office on January 1 of the year succeeding their election or appointment, except that incumbent delegates on the date of the adoption of these By-Laws shall serve until their successors are elected and assume office. Constituent associations entitled to more than one representative shall elect them so that one half the number, as near as may be, are elected each year. Past Presidents of the American Medical Association shall serve for a period of five years immediately following their tenure of the presidency of the American Medical Association.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Robertson Ward, Chairman, submitted the following report, which was duly adopted by a standing vote, and referred by the Speaker to the Interim Committee on Constitution and By-Laws for proper wording:

Resolution presented by Dr. Wall of Mississippi making Past Presidents of the American Medical Association members of the House of Delegates for five years, with power to vote: It will be remembered that a similar resolution, which did not limit membership in the House, was rejected at our last session. It is felt by your committee that the five year limitation included in this resolution has eliminated the objectionable features of the previous resolution, and that this resolution should now be accepted. The acceptance and implementation of this resolution requires the folowing changes in the Constitution:

Article 6, Section 2, referring to the composition of the House of Delegates, shall be changed by substituting a comma for "and" at the end of the second line, and adding to the sentence, after "as the case may be, of the respective service," the words "and the five immediate Past Presidents of the American Medical Association." The following sentence shall be changed to read: "The general officers, the Past Presidents of the Association (excluding the five immediate Past Presidents), the General Manager", etc. Since this is a change in the Constitution, it is now introduced and will have to lay over until the next session, at which time a change in the By-Laws will need to be made.

Resolution on Emeritus and Retired Membership

Dr. Warren W. Furey, Illinois, presented the following resolution, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

Whereas, Many component county and several constituent state medical societies have classes of non-dues-paying members such as retired and emeritus; and

Whereas, Some such members have been relieved of dues because of disability and loss of income; and

Whereas, The recent action of the House of Delegates of the American Medical Association in adopting dues for all members except in hardship cases; and

Whereas, Such membership dues are a hardship in many cases of retired members; and

Whereas, Such membership dues do detract from the honor and distinction accorded emeritus and like members; therefore be it

Resolved, That the House of Delegates of the Illinois State Medical Society be urged to present a resolution to the American Medical Association at its annual meeting, recommending that the Constitution and By-Laws Committee of that body arrange for classes of membership for both retired and emeritus members with relief from payment of dues in the American Medical Association.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Robertson Ward, Chairman, presented the following report, which was duly adopted:

Resolution on Emeritus and Retired Membership: This resolution was approved by the committee in principle and is referred to the Interim Committee on Constitution and By-Laws for implementation.

Resolution on Abolishment of "Fellowship" in the American Medical Association

Dr. George A. Woodhouse, Ohio, presented the following resolution, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

Whereas, There is confusion, misunderstanding and criticism among many members of the American Medical Association regarding "Fellowship"; and

Whereas, In the opinion of many members, "Fellowship" is now unnecessary inasmuch as all active members of the American Medical Association are now provided with issues of The Journal of the American Medical Association and permitted to attend sessions of the American Medical Association as a part of their membership privileges; and

Whereas, Many active members believe that payment of special "Fellowship dues" should not be required of an active member in order for him to become eligible to be a program participant or to serve in the House of Delegates or as an official of the American Medical Association; and

Whereas, The relationship between the American Medical Association and its members would be improved by establishing a single membership classification which would entitle all members to uniform and equal benefits and privileges; and

Whereas, The contention that "Fellowship" is necessary in order to give the American Medical Association certain control over matters of professional conduct and ethics is untenable for the reason that a physician who is unworthy of "Fellowship" is, and should be considered, unfit for membership; therefore be it

Resolved, That the House of Delegates of the American Medical Association in annual session in Atlantic City, June 11 to 15, 1951, favors the elimination of that classification of members known as "Fellowship" and instructs the Board of Trustees to prepare appropriate amendments to the Constitution and By-Laws for action by the House of Delegates at the next session of the American Medical Association.

(For the report of Reference Committee on Amendments to Constitution and By-Laws see its report on Resolution on Establishment of Single Membership Classification.)

Resolution on Dissemination of Health Insurance News

Dr. George A. Woodhouse, Ohio, presented the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

Whereas, Extension of voluntary health insurance is a most important part of the program of the American Medical Association; and

Whereas, Other groups active in this field have the advantage of coordination on a nation-wide level, while the medical profession's activities are planned and implemented in state and county medical societies; and

Whereas, There is no present medium whereby significant progress in this field is brought promptly to the attention of practitioners and to their representatives responsible for fostering and extending voluntary insurance; now therefore be it

Resolved, That the American Medical Association arrange for regular dissemination of health insurance news in a publication of the American Medical Association.

(For report of Reference Committee on Insurance and Medical Service see its report under Report and Supplementary Report of Council on Medical Service.)

Resolution on Distribution of Interns

Dr. George A. Woodhouse, Ohio, presented the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The continuing unequal distribution of interns between the university and non-university hospitals is becoming more glaringly apparent, the university hospitals having one intern to each 21⅓ beds while the non-university hospitals have only one intern to every 60 beds; and

Whereas, The non-university hospitals are caring for 75% of the total patients at present and would be called on to shoulder an even larger percentage of the case load in event of a civilian disaster; and

Whereas, This situation of intern shortage in the non-university hospitals has been referred to a committee of the American Medical Association for study and remedial recommendations; and

Whereas, To date there have been no suggested methods of relief forthcoming from this committee; therefore be it

Resolved, That the American Medical Association Committee on Training of Interns expedite the preparation of a report containing practical suggestions toward the immediate solution of this critical intern problem.

(For the report of the Reference Committee on Medical Education and Hospitals see its report under Resolution on Distribution of Interns previously submitted.)

Resolution on Dissemination of Factual Information Pertaining to the Practice of Medicine

Dr. George A. Woodhouse, Ohio, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, False and misleading information is being disseminated in popular magazines regarding the practice of medicine in hospitals and the policies of the American Medical Association; be it hereby

Resolved, That the American Medical Association be requested to take immediate steps to inform and educate effectively the public, hospital trustees and the medical profession as to the facts pertaining to the practice of medicine in hospitals and the American Medical Association principles governing the same.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, stated that the Reference Committee on Miscellaneous Business recommends the approval of the resolution and the report was duly adopted.

Resolution on Publicizing Plans of American Medical Association

Dr. George A. Woodhouse, Ohio, submitted the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, The prospect of an insufficient number of physicians to serve the people of the United States in the next ten to twenty years has been given widespread publicity through newspapers and magazines and by radio; and

Whereas, The reasons for predicting a shortage of doctors as outlined in these various articles appear reasonable and understandable because of the arguments presented; and

Whereas, The American Medical Association is accused of obstructing plans for increasing the training program for physicians; therefore be it

Resolved, That the American Medical Association prepare specific replies to these arguments, pointing out in detail the plans the Association has to combat or forestall the anticipated shortage and, furthermore, that efforts be made to have statements on this question publicized by the press and radio for the purpose of acquainting the public with the American Medical Association plans.

Resolution on Standards of Qualifications to Permit Physicians to Apply Radium in Hospitals

Dr. E. P. Pendergrass, Section on Radiology, presented the following report, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, The matter of formulating desirable standards of qualifications to permit physicians to apply radium in hospitals has presented a problem to many hospital staffs; and

Whereas, The physicians on such staffs look to the American Medical Association for guidance in matters of this sort; and

Whereas, A committee of radiation therapists has embodied its recommendations in a report on this specific question; therefore be it

Resolved, That the American Medical Association adopt and disseminate the attached report on desirable standards of qualifications to permit physicians to apply radium in hospitals.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. William Bates, Chairman, presented the following report, which was duly adopted:

Your Reference Committee on Medical Education and Hospitals wishes to report on the resolution presented from the Section on Radiology by the delegate from that section, Dr. E. P. Pendergrass. This consisted of a set of standards signed by five members of the American College of Radiology, to formulate desirable standards of qualifications to permit physicians to apply radium in hospitals. These standards are as follows:

Radium element, its disintegration products, as well as radioactive isotopes, should be under the supervision of one certified in radiology or therapeutic radiology.

Any department of radiology recognized for the training of candidates for the certificate in radiology or therapeutic radiology, should have available an adequate supply of radium suitable for surface and interstitial application.

Ideally, such a department should have a physicist qualified in radiation physics by the Board of Radiology, preferably as a full time member of the department; such a physicist to be available in consultation for dosage problems involving radium as well as responsible for the safe housing of radioactive isotopes, the protection of patient and personnel, and the disposal of waste products.

No one shall be permitted to use radium, its derivatives, or radioactive isotopes unless screened and approved by the director of the department.

Where this is not practicable, the house staff should consult the nearest advisory committee on radium and radioactive isotopes, composed of a therapeutic radiologist, a physicist, a gynecologist, a urologist, a surgeon, and an internist, each certified by his respective board.

This committee shall determine who, from experience and training, shall be permitted to use these modalities and under what conditions. If, after permission to use these substances is granted, a staff member applies the same in a manner not consonant with current knowledge, then their use in the future should be denied him.

Just as the chief surgeon supervises the work of the staff surgeons under him, recommending the dismissal of an incompetent operator, similarly the director of the department of radiology, where he is solely in charge of radium and radioactive isotopes or the committee on radium, etc., should have the power to refuse radium and radioactive isotopes to anyone who has proved incompetent in their use.

The American Board of Radiology has for a good while discontinued any effort at certifying persons in the therapeutic use of radium only, recognizing that certification in radiology or therapeutic radiology of necessity entails a knowledge and experience with both x-rays and radium.

The government agencies having to do with providing and lending radium to institutions, such as the National Institutes of Health, insist on the man in charge being certified by the American Board of Radiology before they will provide facilities including radium for use in that institution.

It is true that certification in radiology or therapeutic radiology does not of itself make one a therapeutic radiologist, but such certification or its equivalent would seem to be the minimum requirement for one to be granted the use of radium or its derivatives. Certification plus experience, to be sure, is the ideal.

It is the opinion of this committee that matters of certification in radiation and regulation of standards pertaining thereto are the province of the American Board of Radiology. Other organizations will in the interest of patient care wish to encourage and maintain such standards and dissuade tendencies that would break them down.

The original called for "Where this is not practicable a committee on radium and radioactive isotopes shall be established, composed of a therapeutic radiologist, a physicist, a gynecologist, a urologist, a surgeon and an internist each certified by his respective board."

Your committee feels that if this is to be distributed through the Council on Medical Education and Hospitals, it should read as follows:

Where this is not practicable, the hospital staff should consult the nearest advisory committee on radium and radioactive isotopes, composed of a therapeutic radiologist, a physicist, a gynecologist, a urologist, a surgeon and an internist, each certified by his respective board or of comparable ability.

Your committee commends the Section on Radiology on this suggested set of standards and recommends that this House of Delegates refer this matter to the Council on Medical Education and Hospitals with the recommendation for distribution to hospitals in the United States.

Resolution on Delinquent 1950 Dues

Dr. John K. Glen, Texas, submitted the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The present requirements of membership in the American Medical Association require that all delinquent dues be paid to the Association before such membership may be retained; and

WHEREAS, Through no fault of their own, certain former members of the Association find themselves delinquent in their 1950 dues; and

WHEREAS, These policies in certain circumstances are detrimental to the best interests of the profession and therefore to the public; now be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees to re-evaluate the position of the American Medical Association regarding delinquent 1950 dues.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, reported that the Reference Committee on Miscellaneous Business approves the resolution, and the report was duly adopted.

Resolution on Free Speech

Dr. L. S. McKittrick, Massachusetts, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Freedom of thought and of expression of ideas are fundamental to the way of life of Americans; and

WHEREAS, Free discussion of controversial matters is a carefully guarded prerogative of scientists; and

WHEREAS, It has been alleged by certain critics that the editorial policy of the American Medical Association has resulted in the restriction or exclusion from publication of the views of minority groups of physicians in certain areas of discussion; therefore be it

Resolved, That the House of Delegates directs that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION welcome and provide space for the considered discussion from varying points of view on problems pertaining to medical education and the availability, cost, distribution and organization of medical services.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, submitted the following report, which was duly adopted:

Your reference committee wishes to offer a substitute resolution, which has been accepted by the Massachusetts delegation:

WHEREAS, It has been alleged that minority opinion is restricted or excluded from publication in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION; therefore be it

Resolved, That the House of Delegates of the American Medical Association reaffirms that it is the present policy to publish in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION considered discussion of controversial medical matters submitted by member physicians.

Your reference committee recommends the approval of the substitute resolution.

Resolution on Membership and Fellowship

Dr. L. S. McKittrick, Massachusetts, submitted the following resolution, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

WHEREAS, The distinction between "Fellowship" and "membership" in the American Medical Association is causing dissatisfaction and confusion among members; and

WHEREAS, The relationship between the American Medical Association and its members would be improved by establishing a single membership classification which would entitle all members to uniform and equal benefits and privileges; and

WHEREAS, Circumstances no longer warrant continuation of an artificial, unnecessary and undemocratic distinction between "Fellowship" and "membership"; and

WHEREAS, Harmony among members and efficiency in the organization would be promoted by a discontinuance of the double classification; therefore be it

Resolved, That the House of Delegates of the American Medical Association in annual session at Atlantic City, June 11-14, 1951, favors the elimination of that class of membership known as "Fellowship" and instructs the Board of Trustees to prepare appropriate amendments to the Constitution and By-Laws for action by the House of Delegates at the next session of the American Medical Association.

(For report of Reference Committee on Amendments to Constitution and By-Laws, see its report under Resolution in Single Membership Classification.)

Resolution on Raising Funds

Dr. Warren L. Allee, for the Missouri delegation submitted the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The need for funds for the activities of this Association is of extreme interest to all members of the House of Delegates; therefore be it

Resolved, That the suggestion of Dr. Roland Klemme of St. Louis of a unique method of fund raising be given consideration by this House of Delegates.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Andrew A. Eggston, Chairman, presented the following report which was duly adopted:

Your reference committee has listened intently to the excellent presentation by Dr. Klemme on the subject of fund raising. Because of the possibilities of many entanglements of advertising, business and finance, your reference committee, after due consideration, does not believe that the House of Delegates should consider this matter at this time, and therefore does not approve of the resolution.

Report of Interim Committee on Constitution and By-Laws

Dr. Joseph D. McCarthy, Chairman, presented the following report, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

Your Interim Committee on Constitution and By-Laws presents the following amendments to the Constitution and By-Laws for your consideration.

AMENDMENTS TO CONSTITUTION

The following amendments to the Constitution were introduced at the Clinical Session of the House of Delegates December 5-8, 1950, and are now submitted for your consideration:

Amendment to Article 5, Section 1, (B): This section of Article 5 has been re-edited. The intent has not been altered and your committee recommends that this section be considered during this meeting rather than held over until the next Clinical Session. The re-edited section reads as follows:

Associate membership in the American Medical Association shall be limited to those members of the constituent associations who are ineligible for active membership in the American Medical Association as defined in Article 5, Section 1 (A) and who hold the degree of Doctor of Medicine or Bachelor of Medicine subject to provisions of the By-Laws.

Amendment to Article 5, Section 1: Add the following new paragraph (C): (C) A member shall retain his active or associate membership as long as he complies with the provisions of the Constitution and By-Laws and with the Principles of Medical Ethics of the American Medical Association.

Amendment to Article 6, Section 2: Your committee recommends that amendment to this section of Article 6 be amended to read as follows and be held over until the next session of the House of Delegates inasmuch as an addition has been made by your committee which alters the intent as contained in the section when read during the immediate past Clinical Session.

The general officers, the Past Presidents of the Association, the General Manager, the Assistant Secretary and the Editor of The Journal of the American Medical Association, the chairmen of the several standing committees and two delegates elected by the Student American Medical Association shall be ex officio members of the House of Delegates without the right to vote.

Amendment to Article 6, Section 3: Your committee recommends that the amendment to this section of Article 6 be held over until the next session of the House of Delegates inasmuch as an addition has been made by your committee which alters the intent as contained in the section read during the immediate past Clinical Session:

The number of delegates from the constituent associations shall be proportional to the number of active members of the American Medical Association in the respective constituent associations as provided in the By-Laws.

Amendment to Article 11.—Funds: Dues and Assessments: Amend first sentence to read: Funds may be raised by equal annual dues or by assessment on each of the active members on recommendation by the Board of Trustees and after approval by the House of Delegates.

AMENDMENTS TO THE BY-LAWS

These amendments, introduced today, may be considered for disposition tomorrow by the House of Delegates.

Amendment to Chapter 1, Division One: Reword this Chapter to read:

Members in good standing of the constituent associations of the American Medical Association are eligible for either active membership or associate membership in the American Medical Association, provided they possess the qualifications set forth in Article 5 of the Constitution and after they have been certified officially for enrolment by the secretaries of their constituent associations to the Secretary of the American Medical Association.

Delete the last sentence of this Chapter, which pertains to the revision of the Constitution and By-Laws in 1947 and is now obsolete.

Amendment to Division One, Chapter II, Section 2. Dues: Annual dues may be prescribed for the ensuing calendar year in an amount recommended by the Board of Trustees and approved by the House of Delegates. Each active member shall pay said annual dues to the constituent association for transmittal to the Secretary of the American Medical Association.

Dues will include subscription to The Journal of the American Medical Association.

The Board of Trustees may excuse a member from payment of dues for the following reasons, provided he is fully or partially excused from the payment of local dues by his component and constituent associations.

(A) Members on whom the payment of dues would work a financial hardship. This fact must be certified to by the secretary of the member's component society;

(B) Members retired from practice;

(C) Interns and residents during the first five years following graduation except that the time spent in the military service may be excluded in calculating the five-year limit;

(D) A member temporarily in the Armed Forces. Dues will be remitted and prorated January 1 or July 1 following the date of the member's entrance into military service.

(E) Members over 70 years of age may be excused, on request, from the payment of American Medical Association dues regardless of local dues exemptions.

Amendment to Division Two, Chapter VII, Section 1. Titles: This merely provides recognition of the newly created Section on Military Medicine. Amend so that paragraph 20 reads "Military Medicine" and paragraph 21, "Miscellaneous Topics."

Amendment to Division Three, Chapter IX, Section 1. Delegates: (A) Qualifications.—In order to be eligible for election to membership in the House of Delegates a physician must have been (1) a member of the American Medical Association and a Member Fellow or (2) a Service Fellow of the Scientific Assembly for at least the two years immediately preceding the session of the House of Delegates in which he is to serve.

Amendment to Division 3, Chapter IX, Section 1 (C) by deleting the words "dues paying." This is made so that there will not be conflict with Article 6, Section 3, of the Constitution.

Amendment to Division Three, Chapter IX, Section 1 (E): It is recommended that this section be amended to read: (E) Status After Seating.—A delegate whose credentials have been accepted by the Reference Committee on Credentials and whose name has been placed on the roll of the House shall remain a delegate until final adjournment of that session. If a delegate is unable to be present on account of sickness or any other emergency, his place may be taken by his alternate if approved by the Credentials Committee. After the alternate has been seated he cannot be replaced.

Amendment to Division Three, Chapter X, Section 4:—This amendment has to do with a typographical error. Standing Committees. Delete the word "Councils" from title.

Amendment to Division Three, Chapter X, Section 4 (B): The Secretary of the American Medical Association is an ex officio member of all standing committees; therefore delete the word "Secretary" in line 3, page 30.

Amendment to Division Three, Chapter X, Section 5 (D): Change "(13) Miscellaneous Business" to "(14) Miscellaneous Business" and add a new (13) Medical Military Affairs, to which shall be referred all matters relating to military affairs or civilian defense.

Amendment to Division Three, Chapter 13, Section 4 (C) (E) and (F): This amendment has to do with punctuation. Delete periods and insert semicolons at the end of paragraphs (C), (E), and (F).

RECOMMENDATIONS FROM THE INTERIM COMMITTEE ON CONSTITUTION AND BY-LAWS RELATIVE TO MATTERS REFERRED BY THE REFERENCE COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS AT THE 1950 CLINICAL SESSION OF THE HOUSE OF DELEGATES

The reference committee at the previous session recommended that the resolution of the Rhode Island Medical Society relative to the number of delegates in the constituent associations having fewer than 1,000 members be not adopted but that the problem be referred to the Interim Committee on Constitution and By-Laws for further study. This recommendation was approved by the House of Delegates. Your Interim Committee on Constitution and By-Laws concurs with the decision of the reference committee as adopted by the House of Delegates but at this time is unable to provide a solution of the problem.

Your committee has considered the recommendations of the reference committee regarding the voting rights of ex officio members of committees. An ex officio member, according to Robert's Rules of Order (Revised) has the right to vote unless otherwise specifically prohibited. It is the opinion of your committee that any organization has the right to determine whether or not an ex officio member of a committee has or has not the right to vote. Your committee would point out that in the Constitution and By-Laws of the American Medical Association this practice has been observed.

The Reference Committee on Amendments to Constitution and By-Laws of the immediate past Clinical Session recommended that the resolution introduced by Dr. William R. Brooksher, Arkansas, be referred back to the Interim Committee on Constitution and By-Laws for further study. This resolution had to do with the amendment of Division Three, Chapter XIII, Section 1, of the By-Laws. In this resolution it was recommended that this section be amended to read "The Board of Trustees shall consist of nine elected trustees as provided in Article 7 of the Constitution, the President and President-Elect. The Vice President, the Secretary, the Treasurer, the Speaker, the Vice Speaker, the General Manager and the Editor of The Journal may attend meetings of the Board. Your committee recommends that this resolution be not adopted.

The reference committee also recommended that the Interim Committee on Constitution and By-Laws "interpret and clarify" the term "executive session." Division Three, Chapter IX, Section (C)—(3) of the By-Laws reads as follows: An executive session shall be limited to the members of the House of Delegates as defined in Article 6, Section 2, of the Constitution and to such administrative employees of this Association and of the House of Delegates necessary for the functioning of the House. This section of the By-Laws as interpreted by your committee is definite in its intent, and your Committee is unable at this time to add anything which would provide further clarification.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Robertson Ward, Chairman, presented the following report, dealing with amendments to the Constitution, which was duly adopted and the two amendments to Article 5, Section 1 were declared made to the Constitution while the amendments to Article 6 Sections 2 and 3 hold over until the next session:

The final matter for the consideration of your reference committee was the report of the Chairman of the Interim Committee on Constitution and By-Laws, Dr. Joseph McCarthy of Nebraska. I will reread this report and give the recommendations of the Committee on each item contained therein:

Your Interim Committee on Constitution and By-Laws presents the following amendments to the Constitution and By-Laws for your consideration.

AMENDMENTS TO CONSTITUTION

The following amendments to the Constitution were introduced at the Clinical Session of the House of Delegates Dec. 5-8, 1950, and are now submitted for your consideration:

Article 5, Section 1 (B): This section of article 5 has been re-edited. The intent has not been altered and your Committee recommends that this Section be considered during this meeting rather than held over for the next Clinical Session. The re-edited section reads as follows:

Associate membership in the American Medical Association shall be limited to those members of the constituent associations who are ineligible for active membership in the American Medical Association as defined in Article 5, Section 1 (A) and who hold the degree of Doctor of Medicine or Bachelor of Medicine subject to provisions of the By-Laws.

Your committee approves the above recommendation.

Article 5, Section 1: Add (C):

Your committee recommends adoption of this amendment to Article 5, Section 1 by the addition of "(C) A member shall retain his active or associate membership as long as he complies with the provisions of the Constitution and By-Laws and with the Principles of Medical Ethics of the American Medical Association."

Article 6, Section 2:

Your Interim Committee recommends that this Section of Article 6 be held over until the next session of the House of Delegates, inasmuch as an addition has been made by your committee which alters the intent as contained in the Section when read during the immediate past Clinical Session.

Since the Interim Committee made the change of adding the Assistant Secretary, and since you have just adopted the change involving the immediate five Past Presidents, the following change in the Constitution must lie over until the next Interim Session, and your reference committee so recommends:

The general officers, the Past Presidents of the Association (excluding the immediate past five), the General Manager, the Assistant Secretary, and the Editor of The Journal of the American Medical Association, the chairmen of the several standing committees, and two delegates elected by the Student American Medical Association shall be ex officio members of the House of Delegates, without the right to vote.

Article 6, Section 3:

Your Interim Committee has recommended that this Section of Article 6 be held over until the next meeting of the House of Delegates, inasmuch as an addition has been made by your committee which alters the intent as contained in the section when read during the last Clinical Session.

The number of delegates from the constituent associations shall be proportional to the number of active members of the American Medical Association in the respective constituent associations as provided in the By-Laws.

Your reference committee approves this action.

Dr. Ward then read the report of the committee on the proposed amendments to the By-Laws as follows, which was duly adopted:

Amendment to Division One, Chapter I: Your committee recommends adoption of the amendment to Division One, Chapter I, to read:

Members in good standing of the constituent associations of the American Medical Association are eligible for either active membership or associate membership in the American Medical Association, provided they possess the qualifications set forth in Article 5 of the Constitution and after they have been certified officially for enrolment by the secretaries of their constituent associations to the Secretary of the American Medical Association.

The last sentence of this Chapter as it reads at the present time, which pertains to the revision of the Constitution and By-Laws in 1947, is now obsolete and is recommended for deletion.

The reference committee approved the amendments to Division One, Chapter II, Section 2: Dues, to read:

Annual dues may be prescribed for the ensuing calendar year in an amount recommended by the Board of Trustees and approved by the House of Delegates. Each active member shall pay said annual dues to the constituent association for transmittal to the Secretary of the American Medical Association.

Dues will include subscription to The Journal of the American Medical Association.

The Board of Trustees may excuse a member from payment of dues for the following reasons, provided he is fully or partially excused from the payment of local dues by his component and constituent associations.

(A) Members on whom the payment of dues would work a financial hardship. This fact must be certified to by the secretary of the member's component society;

(B) Members retired from active practice;

(C) Interns and residents during the first five years following graduation, except that the time spent in the military service may be excluded in calculating the five-year limit;

(D) A member temporarily in the Armed Forces. Dues will be remitted and prorated January 1 or July 1 following the date of the member's entrance into military service.

(E) Members over 70 years of age may be excused, on request, from the payment of American Medical Association dues, regardless of local dues exemptions.

Your committee approves of the amendment to Division Two, Chapter VII, Section 1. Titles, which merely provides recognition of the newly created Section on Military Medicine. Amend so that paragraph 20 reads: "Military Medicine" and paragraph 21 "Miscellaneous Topics."

Your committee approves of the amendment to Division Three, Chapter IX, Section I. Delegates, to read:

"(A) Qualifications.—In order to be eligible for election to membership in the House of Delegates, a physician must have been (1) a member of the American Medical Association and a Member Fellow or (2) a Service Fellow of the Scientific Assembly for at least the two years immediately preceding the session of the House of Delegates in which he is to serve.

Your committee approves of the amendment to Division Three, Chapter IX, Section I (C) by the deletion of the words "dues paying" in the first sentence. This amendment is made so that there will not be conflict with Article 6, Section 3 of the Constitution, if adopted at the next session.

Division Three, Chapter IX, Section I (E)—Status After Seating:

Your reference committee recommends adoption of this amendment with addition of two words for clarification, without changing the sense or meaning of this section, so that it will read:

(E) Status After Seating.—A delegate whose credentials have been accepted by the Reference Committee on Credentials and whose name has been placed on the roll of the House shall remain a delegate until final adjournment of that session. If a delegate, once seated, is unable to be present on account of sickness or any other emergency, his place may be taken by his alternate if approved by the Credentials Committee. After the alternate has been seated he cannot be replaced.

The reference committee approves of the deletion of the word "Councils" from the title in Division Three, Chapter X, Section 4.

Your committee approves of the deletion of the words "the Secretary" in line 3, page 30, of Section 4 (B), Chapter X, Division Three, since the Secretary of the American Medical Association is an ex officio member of all standing committees.

Your committee approves of the amendment to Division Three, Chapter X, Section 5 (D) by the deletion of periods and the insertion of semicolons at the end of paragraphs (C), (E) and (F).

RECOMMENDATIONS

Your committee concurs with the decision of the Interim Committee on Constitution and By-Laws with respect to the resolution of the Rhode Island Medical Society at the Cleveland Clinical Session, as follows.

Your present reference committee approves the following definition of ex officio members as submitted by the Interim Committee:

Your interim committee has considered the recommendations of the reference committee regarding the voting rights of ex officio members of committees.

An ex officio member, according to Robert's Rules of Order (Revised) has the right to vote unless otherwise specifically prohibited.

It is the opinion of your committee that any organization has the right to determine whether or not an ex officio member of a committee has or has not the right to vote. This committee would point out that in the Constitution and By-Laws of the American Medical Association this practice has been observed.

The Reference Committee on Amendments to the Constitution and By-Laws at the Clinical Session in December recommended that the Interim Committee on Constitution and By-Laws "interpret and clarify" the term "executive session." Division Three, Chapter IX, Section 3 (C) (3) of the By-Laws reads as follows:

An executive session shall be limited to the members of the House of Delegates as defined in Article 6, Section 2, of the Constitution and By-Laws and to such administrative employees of this Association and of the House of Delegates necessary for the functioning of the House.

This section of the By-Laws as interpreted by your committee is definite in its intent and your committee is unable at this time to add anything which would provide further clarification.

With this, your present reference committee is in complete accord.

Supplementary Report of Board of Trustees Presenting Resolution on Civilian Control of Medical and Health Affairs

Dr. Louis H. Bauer, Chairman, Board of Trustees presented the following resolution from its Council on National Emergency Medical Service, which was referred to the Reference Committee on Emergency Medical Service:

Resolved, That the American Medical Association make clear and unequivocal its belief in the fundamental principle outlined in the National Security Act of 1947 that civil authority must ever govern and control the nation's means of its own defense; and in line with this fundamental principle of our democracy the Association commit its full power and influence to insure perpetuation of the policy established by the first Secretary of Defense, James Forrestal, and reaffirmed and supported in turn by Secretaries Louis Johnson and George C. Marshall to the end that civilian control in medical and health matters shall prevail at the Secretary's level in the Department of Defense through the continuance of the Armed Forces Medical Policy Council and through full authority vested in the civilian Chairman thereof as the Assistant to the Secretary of Defense for medical and health affairs in his office.

REPORT OF REFERENCE COMMITTEE ON EMERGENCY MEDICAL SERVICE

Dr. J. Arnold Bargen, Chairman, presented the following report, which was duly adopted:

Your reference committee approves this resolution with the following amendment:

Instead of the words "full authority vested in the civilian Chairman," which are contained in the last three lines, the words "such authority as is presently vested in the civilian Chairman," be substituted.

Supplementary Report of Board of Trustees on Recommendation on Universal Military Training Act

Dr. Louis H. Bauer, Chairman, submitted the following recommendation of its Council on National Emergency Medical Service, which was referred to the Reference Committee on Emergency Medical Service:

The Congress has passed a Universal Military Training Act. The implementation of this Act will involve substantial readjustments in medical services of the Armed Forces and may have a profound impact on all phases of American medicine. The American Medical Association is interested in the provision of adequate medical and health services for the Armed Forces, also for the civilian population.

This Act provides that a National Security Training Commission be appointed by the President for the purpose of submitting to the Congress within four months a plan for universal military training. In view of the complex and far-reaching medical implications of this Act, the Council on National Emergency Medical Service has recommended to the Board of Trustees that a study be conducted by the American Medical Association of the medical problems involved in the conduct of this universal military training program. The Board of Trustees has adopted this recommendation of the Council on National Emergency Medical Service, and a study will be undertaken immediately with the cooperation of interested groups.

REPORT OF REFERENCE COMMITTEE ON EMERGENCY MEDICAL SERVICE

Dr. J. Arnold Bargen, Chairman, presented the following report, which was duly adopted:

It is the opinion of your reference committee that in view of the urgency of the situation the committee felt that the resolution should be voted on, or the feeling of the House of Delegates expressed at this time.

Supplementary Report of Board of Trustees on Report on Veterans Administration Activities

Dr. Louis H. Bauer, Chairman, Board of Trustees submitted the following report which was referred to the Reference Committee on Emergency Medical Service:

The American Medical Association approves the principle whereby the existing specialist centers within the Veterans Administration are utilized for the care of military personnel so severely disabled that their return to active duty is unlikely.

Report of Reference Committee on Emergency Medical Service

Dr. J. Arnold Bargen, Chairman, presented the following report, which was duly adopted:

Your reference committee is in accord with the expressed statement of the Board of Trustees approving the principle of "what they plan to do."

Supplementary Report of Board of Trustees on Medical Relations in Workmen's Compensation

Dr. L. H. Bauer, Chairman, submitted the following report, which was referred to the Reference Committee on Industrial Health:

In compliance with instructions contained in the Resolution on Medical Relations in Workmen's Compensation passed by the House of Delegates at the 1950 San Francisco Session, the Council on Industrial Health has gotten in touch with the constituent state medical societies, the International Association of Industrial Accident Boards and Commissions, the American Association of Industrial Physicians and Surgeons and the American Academy of Compensation Medicine, with the following results:

1. Approximately 20% of the state medical societies have responded. A later report will be based on completed returns and on proposals discussed later in this report.

2. The International Association of Industrial Accident Boards and Commissions has submitted a list of principles as a basis for establishing better medical relations:

(*a*) There is need for more skilled medical and surgical care for injured workers without limitations of cost or other legal prohibition.

(*b*) The goal of medical care in compensation cases is the maximum reduction of permanent disability, maximum physical restoration and preparation of the injured worker for resumption of gainful employment. In this connection, it is suggested that the chosen physician in any case, though he may confer and refer the injured worker for special services, should continue in nominal charge and assume the responsibility for proper direction in rehabilitation procedure.

(*c*) Close association and cooperation between the compensation administrative agency and the state or local medical groups is essential to procure proper medical attention and to secure written reports and advice necessary for the administrative agency's case records.

(*d*) The trend for medical care in compensation is toward free initial choice of physician, as allowed under the rules promulgated by a given workmen's compensation agency. Further, there should be clear understanding that the direction of legal provisions for medical aid is a compensation administrative problem, and that such direction should be in the agency administering the compensation law, always with the benefit of advice and cooperation of medical groups.

(*e*) Organized undergraduate and graduate educational and training programs are needed for physicians in occupational medicine, traumatic surgery, physical medicine and rehabilitation.

If agreeable to the House of Delegates, the Council on Industrial Health submits this statement as a basis of study and will submit it to the state medical societies as a basis for cooperation with the applicable workmen's compensation authority.

3. The American Academy of Compensation Medicine has suggested:

(*a*) That the House of Delegates urge each state medical society to obtain and maintain complete data on compensation practice by the secretary's office or a special committee as indicated.

(*b*) That copies of this information be sent to the Council on Industrial Health.

(*c*) That these reports be studied by a competent person on the Council's staff with a view toward publication of pertinent findings.

(*d*) That field visits be undertaken to supplement the reports submitted from the states.

The Board of Trustees feels that these proposed principles require considerable further study before they are accepted as final and requests that they be referred back for such further study.

Report of Reference Committee on Industrial Health

Dr. C. E. Wertz, Temporary Chairman, submitted the following report, which was duly adopted:

Your Reference Committee on Industrial Health approves the supplementary report of the Board of Trustees on Medical Relations in Workmen's Compensation, including the principles enunciated therein. It recommends that these principles be used as a basis for further study as suggested by the Board of Trustees. In the course of this study, it is hoped that all of the constituent state associations rather than only the 20% recorded in the report will cooperate with the Board of Trustees.

Supplementary Report of Board of Trustees on Report of Committee on Blood Banks

Dr. L. W. Larson, Chairman, Committee on Blood Banks, presented the following report, which was referred to the Reference Committee on Emergency Medical Service:

In compliance with the action of the House of Delegates a year ago, the Board of Trustees authorized the Committee on Blood Banks to have prepared a brochure on starting and operating a blood bank and a second survey of blood banks. The former, Bulletin 82 of the Bureau of Medical Economic Research, was mailed a few weeks ago to the officers of the Association, the members of the House of Delegates, and to state and county medical societies.

Bulletin 83 of the Bureau of Medical Economic Research, entitled "Second Survey of Blood Banks," is now being distributed to the members of the House. Appendix A of our Committee report today is inserted in Bulletin 83; it provides a brief summary of Bulletins 82 and 83. The preparation of Bulletin 83 is the work of Frank G. Dickinson, Ph.D., Everett L. Welker, Ph.D., and several other members of the staff of the Bureau of Medical Economic Research. The Committee desires to thank the Council on Medical Education and Hospitals for including five questions on blood used and procured in hospitals in its Annual Census of Hospitals for 1950.

The "Second Survey of Blood Banks" clearly establishes that three million units of whole blood were used annually, prior to the Korean conflict, in hospitals for the treatment of patients. Of the three million units, 70% was procured in hospitals, 13% in nonhospital blood banks, and the remaining 17% in Red Cross regional blood centers. The amount of blood procured monthly has, of course, increased rapidly since the start of the Korean conflict.

The Committee reaffirms its belief, which was stated in its report to the House at the 1950 Cleveland Session, that mass blood grouping is inadvisable. The major problem is procurement of blood. This major problem should have general priority over any fringe projects because they divert funds and public attention from the major need. To stimulate procurement, the Committee urges every physician and the members of his family who are acceptable donors to give blood for military and civilian defense purposes through the Red Cross or local blood banks as the latter become affiliated with the national blood program.

The Committee reemphasizes the importance of a committee on blood banks being developed in each state as recommended at the Cleveland Session. It believes that the personnel of the state committees should include representatives of the state medical association, the state pathological society, the state hospital association, the state health department, the Red Cross and the other blood banks located in the state. The state committee should, in addition to other duties, concern itself with developing good working relationships between all types of blood banks in the state. Controversies and difficulties in these relationships should be settled at the local and state level; and those incapable of such adjustment may be referred to the

Committee on Blood Banks of the American Medical Association. It would be the general responsibility of the state committee to assure the smooth operation of the blood program in its state. Specifically may be mentioned the opportunity of the state committee to facilitate the establishment of contracts between qualified blood banks and the National Emergency Blood Program; the allocation of blood for civilian, military and civilian defense uses; the arrangement for limited local storage of plasma, and the increase of blood bank inventories of standard collection sets, bottles and administration sets. In event of an attack in any state, the state committee would immediately function under the direction of the state civilian defense administrator.

As regards the Department of Defense and the Civilian Defense Administration, the attention of the House is redirected for emphasis to the statements made in the Supplementary Report of the Committee to the House at the Cleveland Session. Supplies of whole blood and of blood for fractionation are continuing to flow to the Armed Forces in steadily increasing amounts; the amounts necessary for the fiscal year 1952 will probably be double or triple our current rate.

It is regrettable that the Congress has not yet made available the necessary funds for the development of dispersed federal reserve supplies of plasma for civilian defense and of equipment for collecting and administering blood and plasma.

The American National Red Cross Blood Program now has the following 41 *regional* centers:

Eastern
Buffalo, N. Y.
Burlington, Vt.
Columbus, Ohio
Hartford, Conn.
Ft. Wayne, Ind.
Huntington, W. Va.
Johnstown, Pa.
Louisville, Ky.
Wilkes-Barre, Pa.
Roanoke, Va.
Philadelphia, Pa.
New York, N. Y.
Boston, Mass.
Rochester, N. Y.
Syracuse, N. Y.
Norfolk, Va.
Washington, D. C.

Midwestern
Detroit, Mich.
Lansing, Mich.
Madison, Wis.
Omaha, Neb.
Peoria, Ill.
St. Paul, Minn.
Springfield, Mo.
Wichita, Kan.
St. Louis, Mo.

Pacific
Boise, Idaho
Great Falls, Mont.
Los Angeles, Calif.
Portland, Ore.
Stockton, Calif.
San Jose, Calif.
Tucson, Ariz.
Yakima, Wash.

Southeastern
Asheville, N. C.
Atlanta, Ga.
Charlotte, N. C.
Mobile, Ala.
Nashville, Tenn.
Savannah, Ga.
Columbia, S. C.

The following 7 regional centers may be in operation by July 1952:

Schenectady, N. Y.
New Orleans, La.
Birmingham, Ala.
Houston, Texas
Waco, Texas
Salt Lake City, Utah
Cleveland, Ohio

Three special defense centers are now in operation in:

Kansas City, Mo.
Indianapolis, Ind.
Chicago, Ill.

By September 1 six more defense centers will be opened in:

Baltimore, Md.
Des Moines, Iowa
Fort Worth, Texas
Oklahoma City, Okla.
Jackson, Miss.
Shreveport, La.

By July 1, 1952, four defense centers are planned for:

Cincinnati, Ohio
Pittsburgh, Pa.
Little Rock, Ark.
Memphis, Tenn.

It is the understanding of the Committee that additional centers of either kind are not now contemplated by the Red Cross. Moreover, Red Cross officials have expressed the hope that many more non-Red Cross centers will be developed.

The Committee has continued to cooperate with the National Blood Program notwithstanding the several reorganizations and attempted reorganizations within the American National Red Cross.

Cordial relationships have been established between the Committee on Blood Banks and the new Director of the American National Red Cross Blood Program, Dr. David N. W. Grant, former Air Surgeon of the U. S. Air Force.

The Committee is aware of the continuing problem of donor procurement. In some quarters physicians using blood from Red Cross regional centers are not assuming their responsibility for securing replacement from families and friends. (See Report of the Committee on Blood Banks, San Francisco, June 1950.)

From the above the following specific recommendations are summarized.

1. That physicians and their families be urged to participate as donors for defense and civilian defense purposes.
2. That there continue to be developed state blood committees performing the functions above outlined.
3. That Congress be reminded of the urgent need for appropriations for reasonable federal stores of plasma and equipment for civilian defense.
4. That physicians using blood recognize their responsibility in replacement from families and friends of patients.

REPORT OF REFERENCE COMMITTEE ON EMERGENCY MEDICAL SERVICE

Dr. J. Arnold Bargen, Chairman, presented the following report, which was duly adopted:

The discussion on blood banks concerns itself largely with the method of procurement of blood. Your Reference Committee approves the report of the Committee on Blood Banks.

Report of Committee on Chronic Diseases

Dr. Robertson Ward, Chairman, presented the following report, which was referred to the Reference Committee on Hygiene and Public Health:

At the last meeting of the House of Delegates of the American Medical Association in Cleveland, the problem of alcoholism was referred to our Committee, whereupon it was decided that the problem could best be handled by appointing a subcommittee to deal with the subject. Dr. Milton G. Potter, of Buffalo, N. Y., was designated chairman of the subcommittee and nominated seven other physicians with knowledge and interest in the field of alcoholism representing various geographical areas. All of those nominated were appointed and have accepted their assignments and have participated in the planning of a nationwide program.

Although time and space do not permit that we inform the House of details, the program envisages efforts to stimulate the formation of a physicians' committee in each state to coordinate the activities of state medical societies, to encourage constructive legislation, to cooperate with interested nonmedical groups, to encourage general hospitals to accept and treat acute alcoholism and to stimulate presentation of formal courses in schools of medicine, nursing, social work, law and others. It is also the plan of the subcommittee to cooperate with the Commission on Chronic Illness and to report to the House of Delegates through our Committee.

The chairman of the subcommittee believes that surveys of the problem of alcoholism will soon yield information that will require careful analysis. He advocates that the American Medical Association sponsor a meeting of all national organizations interested in the problem of alcoholism, such as the National Committee on Alcoholism and the Council on Research on Alcoholism of the National Research Council.

Your Committee has kept in touch with activities of the United States Public Health Service in the field of chronic diseases. This has been accomplished largely by conferences with Dr. Robert J. Anderson.

In January of this year the Division of Chronic Disease and the Division of Tuberculosis of the United States Public Health Service were merged as the Division of Chronic Disease and Tuberculosis, with Dr. Anderson as chief.

This new Division is divided into three main sections. The first of these is Field Research, mainly concerned with tuberculosis. It is the epidemiological branch which is interested, for example, in the study of the evolution of tuberculosis in communities, the evaluation of the use of B. C. G. vaccine, the evaluation of treatment methods for tuberculosis (a study entailing cooperative effort by about 70 investigators scattered throughout the United States) and the evaluation of diagnostic methods in tuberculosis.

The second section is for state aid and is also in the tuberculosis field mainly. This section works only with programs that are of established value. Among other functions, it provides consultative services of physicians, nurses, social workers, educators and experts in case registry methods. The section also provides facilities for screening populations by chest roentgenographic studies.

The third section, Program Development, takes over most of the work of the old Chronic Disease Division and is subdivided very much like the old Division into branches for program analysis, heart disease control, rehabilitation, home care and diabetes control. Activities in this section are expected to undergo transferral into one of the other sections, depending on advancement of work in any phase to a point that such transferral is desirable.

Of particular interest to the House is the fact that the present program of the Division of Chronic Disease and Tuberculosis places more emphasis on the evaluation of multiphasic screening technics than on the use of such technics as though their value were already known.

Your Committee had hoped to present an analysis of the budget of the Federal Security Administration for the purpose of appraisal of the magnitude of total federal expenditures in the field of chronic diseases. Because of circumstances outside our control, this portion of our report must be postponed until the next session of the House of Delegates.

Your Committee believes that it has a definite function to perform in stimulating the formation of chronic disease committees in state and local medical societies. In cooperation with the Commission on Chronic Illness we hope to furnish guidance to such local committees in the development of sound plans for the management of chronic diseases. It is also our hope to be able soon to develop and submit to the House a proposed basic policy in the matter of chronic diseases or any extension of public health function.

REPORT OF REFERENCE COMMITTEE ON HYGIENE AND PUBLIC HEALTH

Dr. Louis M. Orr, Chairman, presented the following report, which was duly adopted:

Your committee next reviewed very carefully the report of the Committee on Chronic Diseases and was of the unanimous opinion that the timeliness and all-inclusiveness of this report should receive the whole-hearted approval and enthusiastic support of this House of Delegates.

It is agreed that this committee has a definite function to perform in stimulating the formation of chronic disease committees in state and local medical societies. It is further hoped that cooperation with the Commission on Chronic Illness will be attained in order that sound guidance may be given to such local committees in the development of realistic plans for the management of chronic diseases.

Report of Reference Committee on Rules and Order of Business

Dr. Walter E. Vest, Chairman, presented the following report, which was duly adopted:

Your Reference Committee on Rules and Order of Business recommends that the House recess at 12:30 p. m. and meet again at 1:30 p. m. today. It recommends also that the committees which have further work to do meet immediately after the adjournment of the afternoon session.

Resolution on Stamps of Approval for Iodized Salt Packages

Dr. William A. Hyland, Michigan, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, Endemic goiter is common in many sections of the United States; and

WHEREAS, It has been demonstrated that the use of iodized salt is a good preventive of endemic goiter; therefore be it

Resolved, That the House of Delegates of the American Medical Association instruct the Council on Pharmacy and Chemistry to prepare a stamp of approval by the American Medical Association which the salt manufacturers may use on their iodized salt packages to increase the sale of the same.

REPORT OF REFERENCE COMMITTEE ON HYGIENE AND PUBLIC HEALTH

Dr. Louis M. Orr, Chairman, presented the following report, which was duly adopted:

Your committee is fully aware of the merits of iodized salt for use in certain conditions. It is also cognizant of certain objections to its general use in all sections of the country.

Your committee, therefore, recommends that no action on this matter be taken by the House at this time and that this resolution be referred to the Council on Foods and Nutrition for study and that recommendations by the Council be submitted at the next session of the House of Delegates.

Resolution on Services of Whitaker and Baxter

Dr. George S. Klump, Pennsylvania, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, At the suggestion of Whitaker and Baxter the National Education Campaign will be terminated at the end of 1951; and

WHEREAS, The conclusion of this campaign implies that the services of Whitaker and Baxter will be discontinued at the same time; and

WHEREAS, The services of Whitaker and Baxter have been most effective in promoting the principles of free enterprise; therefore be it

Resolved, That the House of Delegates of the American Medical Association recommends to the Board of Trustees that the services of Whitaker and Baxter be retained in a consultive capacity.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. L. G. Christian, Chairman, presented the following report, which was duly adopted:

The resolution introduced by Dr. George S. Klump has been amended with his approval, and your reference committee recommends approval of it to read as follows:

WHEREAS, At the suggestion of Whitaker and Baxter, the National Education Campaign will be terminated at the end of 1951; and

WHEREAS, The conclusion of this campaign implies that the services of Whitaker and Baxter will be discontinued at the same time; and

WHEREAS, The services of Whitaker and Baxter have been most effective in promoting the principles of free enterprise; therefore be it

Resolved, That the House of Delegates of the American Medical Association express appreciation to Whitaker and Baxter for their excellent campaign in the educational program of the American Medical Association, and hope that their services will be available in case of future need, as deemed necessary by the Board of Trustees.

Gift from Woman's Auxiliary

Dr. Elmer L. Henderson, Past President, reported as follows:

Mr. Speaker and Members of the House of Delegates: I think this is a very important announcement. Each year some of your officers are invited over to have lunch with the Auxiliary. Today I was introduced to the Auxiliary by the President, and she held me down for a minute until the immediate past president got up and presented me with a check for $10,000 to the American Medical Education Foundation.

I don't know whether you realize it, but up until two years ago they only paid 25 cents a year dues. Two years ago their dues were raised to $1. I don't know how they accumulated $10,000, but that certainly does show a wonderful spirit of cooperation.

A motion of thanks was made simultaneously by several delegates, was seconded, and was carried by a spontaneous rising vote, and the Speaker requested the Secretary to see to it that that vote of thanks was telephoned to the women while they were in session.

Resolution on Appointment of Reference Committees

Dr. A. F. R. Andresen, New York, presented the following resolution, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

WHEREAS, We have observed during this session the really remarkable job done by our Reference Committee on Miscellaneous Business with the fifteen resolutions referred to it; and

WHEREAS, This committee worked an entire day and into the night adequately to give consideration to all of the resolutions submitted to it, while some committees had little or nothing to do; and

WHEREAS, A new Reference Committee on Military Affairs was created at this meeting; therefore be it

Resolved, That the House of Delegates request the Speaker to appoint a committee, including, preferably, at least one previous chairman of the Reference Committee on Miscellaneous Business, to investigate and to make recommendations regarding the desirability of either providing for additional Reference Committees on Miscellaneous Business, which could be designated by "A," "B" and "C"; to create new reference committees to relieve the excessive burden on the present lone Reference Committee on Miscellaneous Business, or to consider a reapportionment of all of the reference committees.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS

Dr. Robertson Ward, Chairman, presented the following report, which was duly adopted:

This resolution suggested that because of the multiplicity of measures assigned to the Reference Committee on Miscellaneous Business at this session, additional committees be created to handle miscellaneous business, a committee to help the Speaker assign topics, or a reapportionment of all reference committees be carried out.

Your reference committee recommends that this resolution be not adopted, because the proposals suggested would lead to confusion and detract from the power of the Speaker to assign topics, and because the present assignment of many resolutions to the Reference Committee on Miscellaneous Business is an occasional circumstance which might happen to any reference committee.

Introduction of Dr. E. P. Montgomery

Dr. F. F. Borzell, Speaker, introduced Dr. E. P. Montgomery, Quincy, Illinois, a ninety-three year old practicing physician, and the House applauded.

Telegram to Dr. Henry R. Viets

On motion duly made, seconded and carried, the Secretary was requested to send a telegram to Dr. Henry R. Viets, Chairman of the Council on Scientific Assembly, expressing the good wishes of the House of Delegates for his early recovery.

Telegram to Dr. T. C. Routley

The House received a telegram of good wishes from Dr. T. C. Routley, Secretary of the Canadian Medical Association, and on motion, duly made, seconded and carried, the Secretary was instructed to send a telegram to Dr. Routley, stating that the members of the House of Delegates have missed his friendly presence and wishing him speedy and complete recovery.

Supplementary Report of Board of Trustees

1952 DUES

Dr. Dwight H. Murray, Board of Trustees, presented the following report, which was duly adopted:

The Board of Trustees recommends that the 1952 dues of the American Medical Association be $25. This includes subscription to THE JOURNAL.

PHYSICIANS PLACEMENT SERVICE

Dr. Dwight H. Murray, Board of Trustees, presented the following report, which was adopted without referral:

The American Medical Association has for many years recognized the need for a more equitable distribution of physicians in the United States. In an effort to meet this need, its Council on Medical Service has conducted a Physician Placement Service through which many communities have been assisted in obtaining the services of a physician.

The Board of Trustees believes that there is a definite need for expanding the Association's activities in this field and in providing the leadership to develop further the physicians placement services in the state medical societies, as follows: (1) the organization and implementation of an effective physician placement service in every state; (2) expansion of the present program of the American Medical Association's Physician Placement Service; (3) conducting a national conference on physician placement if found advisable, and (4) design plans for financial assistance to physicians in setting up a practice.

The Board will give support to this program by financing it to the degree demonstrated to be necessary.

LETTER RE DEFERMENTS OF STUDENTS

Dr. Dwight H. Murray, Board of Trustees, presented the following report, and the House duly approved the letter:

The Board of Trustees has authorized that the following letter be sent to Dr. Howard Rusk, Chairman of the Health Resources Advisory Committee in the Office of Defense Mobilization:

The Board of Trustees of the American Medical Association is concerned that the extremely broad provisions for deferments under Section 6 (h) of Title I of the Selective Service Act of 1948, as recently amended by the enactment of Senate Bill 1 by the 82d Congress, will jeopardize acceptance of the necessary deferment of undergraduate and graduate medical students by the local boards of the Selective Service System.

The Board of Trustees urges that your committee recommend to the President and, if appropriate to the Congress, that deferments under this section be limited to persons in those categories for which a need in the armed forces or a shortage in the civilian economy have been specifically established.

PLACE OF 1954 CLINICAL SESSION

Dr. Dwight H. Murray, Board of Trustees, presented the following report, which was declared a responsibility of the Board of Trustees:

The Board of Trustees has selected *Miami, Florida*, as the place for the 1954 Clinical Session of the American Medical Association.

Statement of Speaker

Dr. F. F. Borzell, Speaker, submitted the following statement:

We will now proceed with the regular business of the House, but before we proceed the Speaker is pleased to announce that the Board of Trustees acceded to the expressed wish of the House of Delegates this morning that Whitaker and Baxter be retained. It is understood, of course, that at the conclusion of this year their functions will be directed as previously by the Coordinating Committee and the Board of Trustees to whatever extent the exigencies at that time would indicate.

The Board has also announced that because of the fact of the continuing activity of Whitaker and Baxter they felt it inadvisable to make any changes in the personnel of the Coordinating Committee and therefore by action of the Board the Coordinating Committee personnel will remain the same, including the Chairman, Dr. Henderson, who has very graciously agreed to continue as Chairman of the Coordinating Committee. In other words, he has not expired.

Roll Call

The Secretary called the roll, there being more than a quorum answering.

Election of Officers

The following officers were elected to vacancies:

President-Elect: Dr. Louis H. Bauer, Hempstead, L. I., N. Y.

Vice President: Dr. Oscar B. Hunter, Washington, D. C.

Secretary: Dr. George F. Lull, Chicago.

Treasurer: Dr. J. J. Moore, Chicago.

Speaker, House of Delegates: Dr. F. F. Borzell, Philadelphia.

Vice Speaker, House of Delegates: Dr. James R. Reuling, Bayside, N. Y.

Member, Board of Trustees, to succeed Dr. Walter B. Martin for term ending in 1956: Dr. Walter B. Martin, Norfolk, Va.

Member, Board of Trustees, to succeed Dr. Louis H. Bauer, elected as President-Elect, for a term ending in 1954: Dr. David B. Allman, Atlantic City, N. J.

Committee on Distinguished Service Award appointed by President John W. Cline: Dr. H. Gordon MacLean, Oakland, Calif.; Dr. James S. Stevenson, Tulsa, Okla.; Dr. James M. Faulkner, Boston.

Member, Judicial Council, to succeed Dr. Walter F. Donaldson for a term ending in 1956, nominated by Dr. John W. Cline, President: Dr. Walter F. Donaldson, Pittsburgh, Pa.

Member, Council on Scientific Assembly, nominated by Board of Trustees, to succeed Dr. Samuel P. Newman for a term ending in 1958: Dr. Samuel P. Newman, Denver.

Member, Council on Medical Education and Hospitals, nominated by Board of Trustees, to succeed Dr. W. S. Middleton, who did not wish reelection, for a term ending in 1958: Dr. Franklin D. Murphy, Kansas City, Kan.

Member, Council on Medical Service, nominated by Board of Trustees, to succeed Dr. H. B. Mulholland for a term ending in 1954: Dr. H. B. Mulholland, Charlottesville, Va.

Member, Council on Medical Service, nominated by Board of Trustees, to succeed Dr. Joseph D. McCarthy for a term ending in 1954: Dr. Joseph D. McCarthy, Omaha.

Members of Permanent Committee on Constitution and By-Laws, nominated by Board of Trustees: Dr. James S. Stevenson, Tulsa, Okla., for a term expiring in 1952; Dr. Stanley H. Osborn, Hartford, Conn., for a term expiring in 1953; Dr. Floyd S. Winslow, Rochester, N. Y., for a term expiring in 1954; Dr. B. E. Pickett Sr., Carrizo Springs, Texas, for a term expiring in 1955; Dr. Louis A. Buie, Rochester, Minn., for a term expiring in 1956; the President, the Secretary, the Assistant Secretary, Dr. E. S. Hamilton, Kankakee, Ill., as the member of the Board of Trustees, the Speaker and the Vice Speaker of the House of Delegates, all ex officio members without the right to vote.

Election as Affiliate Fellows:

On nomination of Judicial Council: Dr. David P. Duffie, Juliaca, Peru, S. A.; Dr. Dunbar Wallace Smith, Los Angeles, Calif.

On nomination of Section on Internal Medicine: Dr. William H. Daughaday, St. Louis.

On nomination of Section on Preventive and Industrial Medicine and Public Health: Dr. Howard Stanley Hoyman, Urbana, Ill.

Election as Associate Fellows:

On nomination of Council on Scientific Assembly: The Secretary presented the names of 490 physicians and the House elected them to Associate Fellowship.

Address of President-Elect Louis H. Bauer

The newly elected President-Elect, Louis H. Bauer, was led to the platform and presented the following address:

Mr. Speaker, Members of the House of Delegates:

It is difficult to express my feelings at this time. One would, indeed, be less than human, if he did not feel considerable emotion at being chosen President of the greatest medical association in the world. There is no higher honor that can come to a physician.

I realize that it is not only an honor but that it carries with it arduous duties and tremendous responsibilities. These, I am prepared to accept.

We have passed through a trying period. For the time being we have averted the greatest threat against the freedom of medicine. The fight, however, is not won and we cannot relax. All we have gained is a breathing space. The world is watching to see what we will do with this breathing space. If we sit back and do nothing, we shall have lost our last opportunity.

Now is the time for constructive action. Our voluntary insurance program has made tremendous strides but it is not yet the complete answer. It must be expanded to fill the gaps in coverage which still exist. The whole profession must be brought enthusiastically behind the program. There are still many physicians who do not cooperate in its expansion.

During the past two and a half years we have aroused many of our members from a state of apathy, but there are still many who evince little interest either in the welfare of the profession or the public.

Our Association has been bitterly attacked both from without and from within. Many doctors and many laymen have little idea of what the American Medical Association is or stands for. The blame for this is, perhaps, our own. We have too long delayed in coming close to our individual members and the public. This situation must be remedied and promptly.

Conditions have changed in the past quarter of a century. Doctors and medical societies can no longer be purely scientific in their viewpoints. They must have an interest in the economics of medicine and in the methods of distribution of medical care. They must find out the needs of the people and anticipate them. Both individual doctors and medical societies should be leaders, broad-minded and forward-thinking. Medicine is humanitarian and the needs of the public must come first. There is no room in medicine for the selfish doctor who thinks only of himself and his income.

We must be leaders in the development of community health councils. We must further expand our grievance committees which have been growing rapidly. Panels of physicians must be available everywhere to cover night, holiday and emergency calls. Nothing irritates a citizen more than being unable to obtain a doctor when he needs one. We must assist in the training of auxiliary and technical personnel of which there is a great shortage.

Medical education must be financially supported. We have made an excellent start, but our goal is not yet even in sight. Additional finances are absolutely essential if our medical schools are to maintain their high standards. This support can come from only two sources, private enterprise or government.

The American Medical Association has been long and bitterly attacked because, except for a one-time grant for so-called bricks and mortar, it has strongly opposed Federal aid to medical education. Our stand, however, has now received strong support from the Commission on Financing Higher Education.

The challenge has been made. We have picked up the gauntlet. Now we must make good and we can if every doctor will do his part. Otherwise we face possible ruination of our medical schools.

The American Medical Association early insisted on a program for civil defense and doctors have been in the forefront in the development of this program. The public, however, is apathetic and we can be of great aid in arousing the public to the dangers of possible atomic warfare. Protection against that is everybody's business, not just that of the military and the medical profession.

I am confident that our new program for the public relations of the Association will be productive of much good.

We are moving forward, but it has taken a long time to arouse medicine. Finally the sleeping giant is awakening and our motto, henceforth, must be "Constructive Leadership." I am determined to do all I can to make this motto more than a mere "catchword."

I thank you, more than I can express, for the honor you have conferred on me and for the confidence you have again placed in me. For eight years you have given me positions of responsibility and trust. I have given the best I could to these positions. I pledge to you that I will continue to give you the best I have in me. At this time I wish to pay tribute to my associates on the Board of Trustees. The membership has steadily changed but I wish to tell you that I have never met a group of men more earnest in their endeavors, or more unselfish in their efforts to further the cause of medicine and improve the health of the public than those with whom I have been associated closely for the past seven years. I am proud to have been one of them.

I feel very humble when I recall those who have preceded me in this office. A year from now, when I take up the torch from the hands of Dr. Cline, I hope I can keep it flaming as brightly as have my predecessors. Again, thank you, and God willing, I will not let you down.

Report on American Medical Education Fund

Dr. Elmer L. Henderson, President, American Medical Education Foundation, presented the following report:

Gentlemen, it is needless for me to say that I am delighted at the action of the Board of Trustees, at the request of this House of Delegates, that Whitaker and Baxter be retained. I can't say that I am so delighted about the continuation of the Coordinating Committee as it is at present made up. However, I have never been called on by the profession to do a job that I have not attempted to do the best that I can, and so long as I am Chairman of the Coordinating Committee I promise you that there is not going to be any let up in the fight against compulsory health insurance.

I want just to give you a few words of warning. Our battle is not won, and I hope that no state will feel that the battle is won and that we should give up our educational committees in the various states or that they should let up in any way.

Until after the election in 1952, we cannot afford to take any chances. We have got to be on guard every minute. The forces that are working today and that were working two and a half years ago for compulsory health insurance and for socialized medicine I may say are just as active today as they were then. I was warned in Washington last week by those men who know that they are even more active than they were a few years ago. I just wanted to give you that note of warning.

In regard to the American Medical Education Foundation Fund for aid to medical schools, you know I announced here in this House of Delegates yesterday and showed you a check that I received from the Auxiliary of the American Medical

Association for $10,000. The California Medical Association voted $100,000 to that fund some weeks ago. South Carolina voted $10,000 to the fund.

At a recent meeting of the Medical Society of the State of New York they decided that they were going to undertake to raise $250,000 for this fund.

Now, gentlemen, if we are going to maintain the American way of life, if we are going to defeat socialism in this country, if we are going to defeat socialized medicine, this is a job that we have to do, and it can be done.

Think what it would mean if every doctor in this country would agree to give this fund $100 a year. Think how much money that would mean. That alone would go a long way to solve the problem of the medical schools in this country. Not only that, it would encourage the National Fund really to get out and do a job with industry.

As I told you the other day in my talk, we have joined up in a way with the National Fund of which Former President Hoover is the Honorary Chairman. We had a most enthusiastic meeting in New York on May 16, last month. We of the American Medical Association who were there were very much surprised at the enthusiasm in this meeting. We did not know that they had gone as far as they had toward getting the support of industry, and I believe we are going to be able to do a job, but we are only going to be able to do that job provided the medical profession does its part. Not only should individual doctors throughout this country contribute to this fund, but every state society, every medical organization in this country. You remember the other morning we received a check for $2,000 from the American College of Radiology, and we have received some other donations from smaller organizations. That is the way we can solve one of the problems of socialism in this country, and I hope that each and every one of you will go back to your state and go to work on this education fund and see if we can't really raise a substantial amount.

We have had a number of checks for $200, $250, quite a few for $500, quite a few for $1,000, from individual doctors. We realize that every doctor could not afford to give a large contribution, but if you can't give $100, can't give $50, if you can give $10 it will go a long way toward bringing this fund to a point where it will do a job. I hope that each and every one of you will become interested in this. I hope that each and every one of you will contribute to it personally and go back to your states and work for it. Thank you.

Presentation of Purse to Miss Hattie Niehoff

The Speaker, Dr. F. F. Borzell, addressed the House as follows:

I now have a task to perform which in many ways is an extremely pleasant task, but it is definitely tinged with sincere regret that it is necessary to perform it. I am going to ask Dr. Reuling to assist me. I wish Dr. Reuling would conduct our most efficient and long serving, faithful servant, our chief clerk, *Miss Hattie Niehoff*, to the platform.

Members of the House of Delegates, it is, as I said, with mixed emotions that I announce to you that this is the concluding session that Hattie Niehoff will serve us as she has served us for twenty-seven years in this House and thirty-seven years as a member of the staff of the American Medical Association.

I need not tell you how well Miss Niehoff has served. I need not tell you that the efficiency that has been demonstrated in the management of the affairs of the House of Delegates is in the main due to the hard work that she does prior to the sessions and during the sessions to see to it that we are not only made comfortable but that the machinery is well greased and that things go along smoothly.

I hold in my hand a scroll. That scroll says, "To Miss Hattie A. Niehoff from the Members of the House of Delegates of the American Medical Association, June 14, 1951: This token of our esteem from the members of the House of Delegates is far too small a way to measure our regret at losing your valuable services, kindly advice and sincere loyalty. May the remainder of your life afford you the same happiness that you have given us for the last 37 years."

This scroll contains the names of many of your friends, Hattie, and as a small token of our appreciation and also to provide you with perhaps the means by which you may come back and visit us occasionally we present you this purse.

Miss Niehoff replied: I thank all of you sincerely. I think you know it is almost impossible for me to say anything to express myself except that my work for you has been a pleasure from the time I started. I wouldn't have had it otherwise and I would not have wanted to work with any other group than this one. Thank you.

Vote of Thanks to Atlantic City

A rising vote of thanks was extended to Atlantic City, to Dr. David Allman and to Mr. Harold Baggs for the wonderful reception extended to the delegates and others attending the session.

The House adjourned sine die at 3:05 p. m.

MEDICAL NEWS

ARKANSAS

State Medical Election.—The Arkansas Medical Society at its recent annual meeting installed Dr. Charles R. Henry, Little Rock, as president and elected Dr. Sherod A. Drennen, Stuttgart, president-elect; Dr. Daniel H. Autry, Little Rock, treasurer, and Dr. William R. Brooksher, Fort Smith, secretary.

CALIFORNIA

Appoint Head of Urology Department.—Dr. Willard E. Goodwin, Baltimore, has been appointed chief of the department of urology and assistant professor of surgery at the new University of California at Los Angeles School of Medicine, to be opened this fall. Dr. Goodwin has been a resident urologist at Johns Hopkins University.

Personal.—Dr. Portia Bell Hume, director of the Berkeley State Mental Hygiene Clinic and assistant professor of psychiatry at the University of California Medical School, has been appointed a deputy director of the state department of mental hygiene. She will head the programs of the seven outpatient mental hygiene clinics maintained by the state.

COLORADO

First Board of Health for Denver.—The citizens of the City of Denver have amended their city charter to provide for the establishment of a department of health and hospitals. It further makes provision for a regulatory board to govern the affairs of this new department. This board conforms, in general, to the structure of the State of Colorado Health Laws as they were revised in 1947 by the Sabin Health Act. Thus, for the first time in its 75-year history Denver has an official board of health. Dr. James P. Dixon has been selected to direct the activities of the new department.

DISTRICT OF COLUMBIA

Program for Training Practical Nurses.—A practical nurse training program has been approved by George Washington University and the District of Columbia public school system. The first group of practical nurse students under this agreement began hospital training at the George Washington University Hospital June 4. This new practical nurse training opportunity has been developed to help relieve the nursing shortage in this area. The program will make Anna Burdick Vocational High School graduates eligible for civil service appointments in government hospitals as well as supply graduate practical nurses to private hospitals in this area. Under the program students may train for 17 weeks at Burdick Vocational High School, where they receive instruction in bacteriology, sanitation, hygiene, anatomy, chemistry, foods and nutrition, physiology, diseases, and record-keeping. They also are acquainted with general health needs, care of the convalescent and mildly ill, care of long-term illnesses, mothers and newborn infants, first aid, and emergency needs. Training at the hospital includes 32 weeks of medical nursing (280 hours), surgical nursing (280 hours), obstetrical and nursery nursing (240 hours), pediatric nursing (160 hours), evening and night services (120 hours), dietetics (80 hours), and urology (120 hours). The university will provide a stipend of $25 a month to each student while she is in training at the hospital.

FLORIDA

Public Health Workers' Academy.—Twelve public health physicians in the state formed the Florida Academy of Preventive Medicine and Public Health in Jacksonville June 19. The new organization, reported to be the second of its kind in the nation (North Carolina was first), has elected Dr. George A. Dame, director of the Bureau of Local Health Services for the Florida State Board of Health, Jacksonville, president; Dr. Turner E. Cato, director of the Dade County Public Health Department, Miami, vice president, and Dr. Frank M. Hall, Alachua County Health Department director, Gainesville, secretary-treasurer. The purpose of the group, says Dr. Dame, is "to encourage the study, improve the practice and advance the cause of preventive medicine and public health."

ILLINOIS

Public Health Appointment.—Dr. Jackson P. Birge has been appointed health officer of the Illinois Department of Public Health's northwest region, with headquarters in Rock Island. Since 1948 he has served as a district health officer for the Indiana State Board of Health and as health officer of the Elkhart (Ind.) County Health Department.

Association of Blood Banks.—Physicians interested in blood banks and representatives of the larger blood banks in the state met May 23 in Chicago to organize the Illinois Association of Blood Banks. This society is organized as a nonprofit organization for the following purposes: (1) to promote and foster the exchange of ideas and materials and the dissemination of information relating to blood banking and its technical methodology; (2) to plan for and foster cooperation in times of disaster; (3) to function as a clearing house on questions relating to training of personnel common to such institutions; (4) to encourage high standards of service, and (5) to promote, aid, and encourage extension of similar services throughout the state. Elected officers are Dr. Israel Davidsohn, Chicago, president; Dr. Max Appel, Champaign, vice president, and Dr. A. M. Wolf, Chicago, secretary-treasurer. President-elect is Dr. George Milles, Chicago.

Chicago

Society News.—At the annual meeting of the Chicago Society of Internal Medicine May 28 the following officers were elected: Dr. Frank B. Kelly, president; Dr. Lowell T. Coggeshall, vice president, and Dr. Ernest G. McEwen, secretary-treasurer.——The Chicago Gynecological Society on June 15 elected the following officers: Dr. M. Edward Davis, president; Dr. Edward M. Dorr, president-elect; Dr. Edwin J. De Costa, secretary, and Dr. Harry Boysen, treasurer.

Dr. Shambaugh to Head Department.—Dr. George E. Shambaugh has been named professor and chairman of the department of otolaryngology at Northwestern University Medical School, effective Sept. 1. He will succeed Dr. Howard C. Ballenger, who will devote full time to his private practice and to revision of a medical textbook. Dr. Shambaugh has been associated with the Northwestern Medical School since 1941. He also is chief of Wesley Memorial Hospital's division of otolaryngology.

Grants for Research.—Three Chicago organizations and companies have awarded grants to the University of Illinois College of Medicine in support of research investigations: Asthmatic Children's Aid, $10,000 in support of histochemical and immunological studies to be conducted under the supervision of Dr. Ben B. Rappaport; Swift and Company, $8,250 for a study of the relationship of bile to cholesterol to be conducted under the direction of Dr. Andrew C. Ivy, and G. D. Searle and Company, $5,540 in support of a study undertaken by Dr. Michael H. Streicher of the effect of beta-diethylaminoethyl xanthene-9-carboxylate (banthine®) on the motility of the small and large intestines.

Instructorship Awards.—Fourth-year students in the University of Illinois College of Medicine have presented Dr. Frederick W. Hiss and Dr. Carl J. Marienfeld with the Raymond B. Allen Instructorship Awards for the 1950-51 school year. The awards,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

designed to honor excellency in individual instructorship given by faculty members to students, are presented annually by each class in the college of medicine. Dr. Morris Green and Dr. Max Samter were presented with awards by the third-year class. Dr. Earl W. Cauldwell received the second-year award, and Parke H. Simer, Ph.D., received the award from the first-year class. Each of the award winners received a key in the form of a golden apple. Their names will be placed on the permanent plaque, which hangs in the Chicago Illini Union.

KANSAS

Personal.—Dr. Eldred V. Thiehoff, chairman of the department of public health and preventive medicine at the University of Kansas School of Medicine, Kansas City, has accepted an appointment to the editorial staff of *Excerpta Medica.* This nonprofit organization seeks to publish abstracts of articles from every available medical journal and is located in Amsterdam, the Netherlands. Dr. Thiehoff will be an editor in Section 4, Medical Microbiology and Hygiene.

Appoint Head of Neurosurgical Section.—Dr. William P. Williamson, associate in surgery, University of Kansas School of Medicine, Kansas City, became full-time chief of the section of neurosurgery on July 1 succeeding Dr. Frank R. Teachenor, who has directed the neurosurgery section since its organization in 1924. Dr. Teachenor, although giving up administrative duties, will continue teaching and clinical research at the medical center in Kansas City. Dr. Williamson joined the faculty in 1945. During 1941 and 1942 he served as a captain in the Army Medical Corps. From 1942 to 1945 he held a residency in neurosurgery at the Neurological Institute, New York. In addition to staff appointments in private hospitals in the city, he has been attending neurosurgeon at Children's Mercy Hospital.

LOUISIANA

Dr. Talbot Honored.—At the meeting of the Louisiana State Medical Society in May a bronze plaque was presented to Dr. Paul T. Talbot, New Orleans, "in appreciation of 33 years of meritorious, valuable and faithful service as secretary-treasurer" to the society. Dr. Talbot retired last year.

Society News.—The Louisiana Diabetes Association at its annual meeting in May re-elected Dr. Arthur A. Herold Sr., Shreveport, president, and Dr. Manuel Gardberg, New Orleans, vice president. Dr. Arthur A. Herold Jr., Shreveport, was chosen secretary-treasurer. Dr. Seale Harris, Birmingham, Ala., spoke on diabetes and hyperinsulinism.

State Medical Election.—At the annual meeting of the Louisiana State Medical Society May 9 Dr. Edwin L. Zander, New Orleans, was installed as president. The following were elected: Dr. William E. Barker, Plaquenine, president-elect; Dr. Charles B. Odom, New Orleans, first vice president; Dr. H. Whitney Boggs, Shreveport, second vice president; Dr. C. Grenes Cole, New Orleans, re-elected secretary-treasurer; Dr. Andrew V. Friedrichs, New Orleans, re-elected chairman of the house of delegates, and Dr. H. Ashton Thomas, New Orleans, re-elected councilor of the First Congressional District.

MARYLAND

Personal.—At the annual meeting of the Medical and Chirurgical Faculty of Maryland April 25 Dr. John H. Hornbaker, Hagerstown, was elected a member of the board of medical examiners of Maryland to serve until June, 1955. Dr. Hornbaker succeeds Dr. W. Allen Griffith, Berwyn, retired.

Drs. Long and Schoenbach Leave Johns Hopkins.—Dr. Perrin H. Long, director of the department of preventive medicine, and Dr. Emanuel B. Schoenbach, associate professor of preventive medicine, at Johns Hopkins University School of Medicine, Baltimore, have accepted appointments at the new State University of New York College of Medicine, which is being developed in Brooklyn. Dr. Long will be professor and executive officer of the department of medicine. From 1929 to 1940 he was associate and associate professor in the department of medicine at Johns Hopkins and became professor and director of the department of preventive medicine in 1940. Dr. Schoenbach will become professor of medicine Aug. 1. He will also be director of the medical services at the Maimonides Hospital in Brooklyn. He has been associated with Johns Hopkins since 1946.

MASSACHUSETTS

Dr. Bauer Appointed Jackson Professor.—Dr. Walter Bauer has been appointed Jackson Professor of Clinical Medicine at Harvard Medical School and chief of medical services at Massachusetts General Hospital, Boston, effective July 1. He succeeds Dr. James H. Means, who has held both posts since 1923. Dr. Bauer is currently associate professor of medicine at Harvard and physician at the hospital. The professorship was named in memory of Dr. James Jackson, who was Hersey Professor in the Harvard Medical School from 1812 to 1836 and was a founder and the first physician of Massachusetts General Hospital. In 1924 Dr. Bauer became medical resident of Massachusetts General Hospital and in 1926 was appointed research fellow in medicine at Harvard Medical School. He has been associated with both institutions since that time.

MINNESOTA

Dr. Spink to Lecture in Europe.—Dr. Wesley W. Spink, Minneapolis, University of Minnesota professor of medicine and consultant on brucellosis for the World Health and the Food and Agricultural organizations of the United Nations, will spend July and August in England, France, Italy, and Yugoslavia correlating current brucellosis research. Dr. Spink is director of the United States Brucellosis Center at the University of Minnesota. His work in Europe was described by Dr. Spink as a cooperative health effort on an international basis designed to bring together information of the various brucellosis research centers for the benefit of each country. Dr. Spink left Minneapolis June 23 for London, where he will give an address before the International Congress of Clinical Pathology July 18. He will speak before the microbiology section on "Some Clinical Problems Relating to the Laboratory Control of Chemotherapy."

MISSOURI

Chest Physicians Meeting.—The following program was presented before a recent meeting of the Missouri chapter of the American College of Chest Physicians in Kansas City.

Dr. Gideon O. Proud, Kansas City, The Sinuses and Bronchiectasis.
Dr. Andrew L. Banyai, Milwaukee, Potentialities of Artificial Pneumoperitoneum.
Dr. Corrin H. Hodgson, Rochester, Minn., Diagnosis and Management of Circumscribed Lesions of the Lung.

An x-ray conference was held with Dr. Lawrence E. Wood of Kansas City as moderator. The following officers were elected: Dr. Elmer E. Glenn, Springfield, president; Dr. Lawrence E. Wood, Kansas City, president-elect, and Dr. Alexander J. Steiner, St. Louis, secretary-treasurer.

Evarts Graham Becomes Professor Emeritus.—Dr. Carl A. Moyer, professor of surgery and dean of the Southwestern Medical College in Dallas, Texas, has been appointed Bixby Professor of Surgery and head of the department of surgery at Washington University School of Medicine, St. Louis, succeeding Dr. Evarts A. Graham. Dr. Graham, who will become professor emeritus of surgery, will remain in St. Louis and continue to be connected with Washington University and the affiliated hospitals in the medical center. At present he is visiting in Glasgow, Scotland, where he received an honorary degree during ceremonies celebrating the 500th anniversary of the University of Glasgow. Dr. Moyer plans to assume his duties at Washington University Medical Center in October. In 1941 he was appointed instructor in surgery at Michigan and was promoted to assistant professor in 1943. From 1944 to 1946 he was surgical director of Wayne County General Hospital, Detroit. Since 1946 he has been professor of experimental surgery at Southwestern Medical College in Dallas and about a year ago became dean. Dr. Graham came to Washington University staff 32 years ago. He is one of the world's leading figures in the field of surgery and has been called the "father of modern chest surgery." In 1933 he performed the first operation for successful removal of an entire lung in one stage for treatment of cancer of the lung. Among his numerous honors and awards is the Distinguished Service Medal of the American Medical Association, awarded at the San Francisco meeting in 1950 (The Journal, July 8, 1950, page 901).

NEW YORK

Public Health Appointment.—Dr. John Browe has been promoted to director of the bureau of nutrition of the New York State Health Department, with which he has been associated since 1949. Dr. Browe has been clinical director of a nutrition study in Burlington, Vt., and research associate in the University of Vermont Medical School. He also was consultant in nutrition to the U. S. Public Health Service before joining the state health department.

Personal.—Arthur Knudson, Ph.D., associate dean and professor of biochemistry at Albany Medical College, has been granted a year's leave of absence to teach in the two medical schools at Bangkok, Thailand (Siam). He left for Bangkok June 25. Dr. Knudson's Bangkok assignment was the result of his earlier appointment as a visiting professor to the Washington University School of Medicine in St. Louis. In conjunction with the United States Economic Cooperation Administration, Washington University has developed a reciprocal teaching program between the faculties of its school of medicine and those of the two medical schools in Thailand.

New York City

Institute of Geriatrics.—The new two million dollar Max and Bertha Weinstein Pavilion, a home for 150 elderly persons and a laboratory for research into problems of the aged, was dedicated in the Bronx May 27. The building was named in honor of the late Max and Bertha Weinstein, who helped maintain the institution for the aged.

Fund to Help the Aged.—The Mayor's Advisory Committee for the Aged has received a $25,000 grant from the Rockefeller Foundation for research on facilities for the aged in the city. Louis I. Dublin, Ph.D., a vice president of the Metropolitan Life Insurance Company, is head of a subcommittee to carry out the one-year study. The committee will try to determine what can be done to prevent the debilities of old age and at the same time utilize the abilities of the group. Persons over 65 in New York represent 7.3% of the population.

Appoint Assistant Dean.—Dr. Joseph M. Pisani has been appointed assistant dean and instructor of medicine at the College of Medicine at New York City, State University of New York. He has been associated with the George Washington University Hospital and School of Medicine as clinical instructor in medicine and is executive director of the committee on medical sciences of the Research and Development Board, Washington, D. C. Dr. Pisani entered military service in 1943 and for 16 months was overseas with the Fifth Army in North Africa and Italy. Dr. Pisani's father, who has been in general practice in New York for over 50 years, and two brothers also are physicians.

OKLAHOMA

State Medical Election.—Dr. L. Chester McHenry, Oklahoma City, became president of the Oklahoma State Medical Association at a meeting in Tulsa in May. Officers elected include: Dr. Alfred R. Sugg, Ada, president-elect; Dr. Allen Gibbs, Oklahoma City, vice president; Dr. Clinton Gallaher, Shawnee, speaker of the house of delegates, and Dr. John F. Burton, Oklahoma City, delegate to the American Medical Association, with Dr. William W. Cotton, Poteau, vice delegate. Dr. Lewis J. Moorman, Oklahoma City, was re-elected secretary-treasurer.

PENNSYLVANIA

Cancer Detection Program.—The Medical Society of the State of Pennsylvania has asked its members to join in a plan to emphasize that every doctor's office is a cancer detection center. "Every physician in Pennsylvania is being asked to make available a 'five-point' cancer detection examination to each of his patients at their request at least once a year," declared Dr. Harold B. Gardner, Pittsburgh, president of the society. "Doctors who are willing and able to cooperate will display a plaque in their recepton rooms so that their patients will know that they can request this service at a fee to be established by the individual physician." The Five-Point Cancer Detection Examination Program was planned by three Pennsylvania cancer-fighting agencies: the commission on cancer of the medical society, the cancer control division of the department of health, and the Pennsylvania Division of the American Cancer Society. The Philadelphia Division of the American Cancer Society, in cooperation with the cancer committee of the Philadelphia County Medical Society, began a similar program several months ago. At the present time more than 1,000 physicians are participating in the Philadelphia area alone. The state local, and county medical societies will inform the local newspapers when the physicians in their communities are prepared to initiate this program.

Philadelphia

Dr. Gordon to Head Women's Medical College.—Dr. Burgess Lee Gordon, clinical professor of medicine at Jefferson Medical College, will become the first full-time, paid president of the century-old · Woman's Medical College of Pennsylvania. Dr. Gordon will organize an industrial health division to make the college and its hospital at Henry Ave. and Abbottsford Rd. more useful in that highly industrialized area. For the division's facilities and personnel and for those of another scheduled new division on geriatrics the college is expected to seek more than three million dollars from the public. Heretofore the presidency has been on an honorary, part-time basis without salary. Academic direction of the college has been generally vested in its deans, who, since 1886, have all been women. The present dean, Marion S. Fay, Ph.D., will continue as head of the faculty. The new president said it was planned to build up and expand all departments in the college and to encourage research.

WEST VIRGINIA

Society News.—Dr. David C. Prickett, Lumberport, was elected president of the West Virginia Public Health Association at its annual meeting held in Huntington May 3-5. Dr. Prickett is health officer for District No. 4.——Dr. Arthur C. Chandler, Charleston, was named president of the West Virginia Academy of Ophthalmology and Otolaryngology at the annual spring meeting April 27-28. Dr. Melvin W. McGehee, Huntington, was named president-elect, and Dr. Keith E. Gerchow, Morgantown, treasurer. Dr. Ben W. Bird, Princeton, was reelected secretary.

State Medical Meeting.—The annual meeting of the West Virginia State Medical Association will be held at the Greenbrier, White Sulphur Springs, July 19-21 under the presidency of Dr. Frank J. Holroyd, Princeton. Out-of-state speakers include the following:

Arnold S. Jackson, Madison, Wis., Cysts and Tumors of the Neck.
Henry R. McCarroll, St. Louis, Common Orthopedic Problems Which Can be Managed in the General Practitioner's Office.
George E. Burch, New Orleans, Water and Electrolyte Balance.
Ralph M. Tovell, Hartford, Conn., Recent Trends in Anesthesiology.
Arthur R. Colwell, Evanston, Ill., Diagnosis and Treatment of Diabetic Acidosis.
Stewart Wolf Jr., New York, Relation of Life Stress to Organic Disease.
LeRoy H. Sloan, Chicago, A Composite Picture of Hypertension.
Oscar Swineford Jr., Charlottesville, Va., Role of the Practitioner in the Management of Asthma.
Emil Novak, Baltimore, Primary Dysmenorrhea.
Frank E. Adair, New York, Hormone Therapy in Cancer of the Breast.
John A. Campbell Colston, Baltimore, Papillary Tumors of the Renal Pelvis and Ureter with Special Reference to Operation o nthe Solitary Kidney, with Case Presentations.

The president's address, "Prophylaxis of Ewingism," will be given Thursday evening. Dr. John W. Cline, San Francisco, President of the American Medical Association, will speak Friday at 7 p. m. on "Problems Facing American Medicine in the Immediate Future." The cancer committee of the association will hear Dr. Adair as their guest speaker Saturday at 2 p. m. The annual banquet will be held Saturday at 7 p. m.

GENERAL

Examinations in Pathology.—The American Board of Pathology will hold examinations at Northwestern University Medical School, Chicago, Oct. 11-13. The first day and a half will be devoted to pathological anatomy and the second day and a half to clinical pathology.

Meeting of Physicians in Alcoholics Anonymous.—The second international conference sponsored by the physician members of Alcoholics Anonymous will be held in Clayton, N. Y., at the Hubberd Hotel August 4-5. The conference will deal with the medical problems of alcoholism. All physicians interested in the problem are cordially invited to address acceptance to Dr. Clarence R. Pearson, 8 Brown Ave., Scottsville, N. Y.

Industrial Medicine Society Changes Name.—The American Association of Industrial Physicians and Surgeons was rechristened the Industrial Medical Association at the annual meeting in Atlantic City, N. J. The society chose as officers for the coming year Dr. Adolph G. Kammer, Pittsburgh, president, and Dr. Earle A. Irvin, Detroit, president-elect. Dr. Arthur K. Peterson, Chicago, continues as secretary and Dr. Edward C. Holmblad, Chicago, as treasurer and managing director.

Rockefeller Foundation Divisions Merge.—A new division of medicine and public health was established in the Rockefeller Foundation June 1 under the direction of Dr. Andrew J. Warren, who has been with the foundation since 1921. The division represents a merger of the former international health division with the former division of medical sciences. Dr. Alan Gregg, who has for 20 years been director for the medical sciences, has been made vice president. Dr. Warren has been head of the international health division since 1945.

Career Research Investigator Appointed.—Dr. Victor Lorber, associate professor of biochemistry at Western Reserve University, Cleveland, has been appointed the first career investigator of the American Heart Association. The career investigator is free to engage in research of his own choosing. He may work in any institution in the United States that offers adequate facilities. As the income of the American Heart Association increases, it will undertake the financial support of a growing number of career investigators. Dr. Lorber was assistant professor, department of physiology, at the University of Minnesota, Minneapolis, from 1944 to 1946.

Tuberculosis Society Elections.—Three tuberculosis societies held annual meetings in Cincinnati May 14-18 and chose the following officers. The National Tuberculosis Association installed Dr. Alton S. Pope, Boston, as president; Dr. Sidney J. Shipman, San Francisco, president-elect; Kemp D. Battle, Rocky Mount, N. C., secretary, and Collier Platt, New York, treasurer. The American Trudeau Society, medical section of the NTA, installed Dr. John H. Skavlem, Cincinnati, as president; Dr. David A. Cooper, Philadelphia, president-elect, and Dr. John D. Steele, Milwaukee, secretary-treasurer.—Robert W. Osborn, New Rochelle, N. Y., assumed the presidency of the National Conference of Tuberculosis Workers, and Mrs. Dalrie S. Lichtenstiger, Los Angeles, was named president-elect.

Dr. Martha Eliot Resigns from WHO.—The resignation of Dr. Martha Eliot as assistant director-general of the World Health Organization in charge of advisory services was announced in June. She will be replaced by Dr. Marcellino Gomes Candau, who is at present director of the WHO division of organization of public health services. Before she joined the staff of WHO in June, 1949, Dr. Eliot was associate chief of the U. S. Children's Bureau. For many years she has been active in international health work. Dr. Candau, who joined the World Health Organization about a year ago, will direct all the services rendered by WHO to countries through public health teams, disease control demonstrations, consultants, training centers, and fellowships. Before coming to WHO, Dr. Candau was superintendent of the Service Especial de Saude Publica, a cooperative public health program of the Brazilian government and the Institute of Inter-American Affairs.

Schering Award Winners.—Dr. Solomon I. Griboff, New York, serving an internship at New York City's Mt. Sinai Hospital, is the winner of the Schering Award for 1950. Dr. Griboff, a senior medical student at Syracuse University College of Medicine when he enrolled in the competition, was presented a check for the first prize of $1,000 for his paper on "The Clinical Use of Steroid Hormones in Cancer." Co-authors Robert W. Winters and Henry M. Williams, both third year students at Yale University School of Medicine, New Haven, Conn., were selected in a tie for second prize with Kenneth J. Ryan, third year student at Harvard Medical School, Boston. They were awarded duplicate prizes of $500 each. Monte J. Meldman, third year student at Marquette University School of Medicine, Milwaukee, was awarded the third prize of $300. Twenty-five contestants received honorable mention, and each received special awards in acknowledgement of their contributions.

Rehabilitation Manual on Multiple Sclerosis.—The National Multiple Sclerosis Society is distributing a 54-page physician's manual entitled *Multiple Sclerosis—Application of Rehabilitation Techniques* by Dr. Edward E. Gordon of New York University-Bellevue Medical Center. This manual was made possible by a grant to the society from the Barnes Foundation, Bristol, Conn., and a gift in memory of Percy Rivington Pyne Jr., of Bernardsville, N. J. It was developed under the direction of Dr. Howard A. Rusk, New York. The manual is designed to facilitate rehabilitation at home. The new manual includes tests with directions for scoring in order to enable the physician to evaluate the extent of disabilities. Activities of daily living are given special emphasis in the manual, with suggestions on the use of specially constructed devices to increase the patient's ability to ambulate in his home. Chapters are devoted to the use of crutches and wheel chairs. Another section deals with means of coping with bladder and bowel difficulties.

Tuberculosis Mortality in the United States.—The U. S. Public Health Service has reported that the nation's death rate from tuberculosis dropped about 9 per cent in 1949 to 26.2 per 100,000 population. A further decline of 15 per cent occurred during the first 11 months of 1950 when the provisional rate (based on a 10 per cent sampling of death certificates) was 22.6 per 100,000 population. With the exception of a slight increase during the 1917-18 influenza epidemic, the death rate for all forms of tuberculosis has shown a downward trend for almost half a century. The death rate for respiratory tuberculosis has decreased 86 per cent, from 174.5 per 10,000 population to 24.5. Despite this decrease, respiratory tuberculosis constitutes over 90 per cent of all deaths from the disease. In 1949 the death rate for men from this cause was 32.5, almost twice as high as the death rate for women, 16.6. The death rate for other forms of tuberculosis has declined from 19.9 to 1.7 per 100,000 population. Mortality rates from tuberculosis continue to be more than three times as high for the nonwhite groups as for the white.

WHO's Executive Board Session.—The executive board of the World Health Organization will convene its ninth session at Geneva beginning Jan. 21, 1952, under the chairmanship of Jacques Parisot, France. The principal decisions taken during the eighth session include the following: The 1951 expenditure level was raised from $6,150,000 to $6,497,400 to provide relief for the civilian population of Korea and for Turkish refugees from Bulgaria. Emergency action was taken to help prevent epidemics in the famine-stricken areas of India, and $30,000 was appropriated for the purchase of medical supplies to prevent outbreaks of cholera and malaria in North Bihar. The board appointed Dr. I. C. Fang regional director of the Western Pacific area with headquarters in Manila, P. I., and authorized the establishment of an African regional organization, which will serve countries and territories south of the Sahara. The board requested that work be initiated on four new international health regulations to deal with the following problems: (1) the control of malaria insect vectors in international traffic, (2) sanitation standards at airports, (3) international pharmacopoeia, and (4) legal protection of international nonproprietary names of drugs. The board also asked WHO to continue its study of population problems, particularly those aspects that pertain to health, including measures for the control of population increases.

MEETINGS

National Medical Association, Philadelphia, Aug. 20-24. Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va., General Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Reno Surgical Society Conference, Riverside Hotel, Reno, Nev., Aug. 23-25. Dr. Olin C. Moulton, 130 N. Virginia St., Reno, Nev., Chairman.

Rocky Mountain Radiological Society, Denver, Aug. 9-11. Dr. Maurice D. Frazer, 1037 Stuart Building, Lincoln, Nebr., Secretary.

West Virginia State Medical Association, The Greenbrier, White Sulphur Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

Association Internationale de Psychotechnique, Gothenburg, Sweden, July 24-28. Dr. Franziska Baumgarten-Tramer, Thunstrasse 35, Berne, Switzerland.

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6^e, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19. Mrs. Grace E. O'Neill, Division of World Affairs, National Association on Mental Health, 1790 Broadway, New York 19, N. Y.

International Congress of Physical Medicine, London, England, July 14-19. Dr. A. C. Boyle, 45, Lincoln's Inn Fields, London, W.C.2, England, Honorary Secretary.

International Congress of Psychology, Stockholm, Sweden, July 16-21. Secretariat: Psychological Institute, Observotoriegatan 8, Stockholm, Sweden.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan American Congress on Tuberculosis, Guayaquil and Quito, Ecuador, S. A., July 14-22. Dr. Marco Martinez M., Casilla de Correos No. 116, Guayaquil, Ecuador, Secretary General.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physical Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Arizona:* *Examination.* Phoenix, July 17-19. *Reciprocity.* Phoenix, July 21. Sec., Dr. J. H. Patterson, 316 W. McDowell Road, Phoenix.

California: *Written.* San Francisco, Aug. 20-23. *Oral.* Los Angeles, August 18. *Oral and Clinical Examination for Foreign Medical School Graduates.* Los Angeles, August 19. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* *Reciprocity.* Denver, July 10. Sec., Dr. George H. Gillen, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, July 10-11. Sec. to the Board, Dr. Creighton Barker, 160 St. Ronan St., Hartford. *Homeopathic.* Derby, July 11-12. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 19. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

Georgia: Atlanta, June. August, Oct. 9-11. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Hawaii: *Examination.* Honolulu, July 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, July 9-11. Sec., Mr. Armand L. Bird, 305 Sun Bldg., Boise.

Maine: Augusta, July 10-11. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Massachusetts: *Examination.* Boston, July 10-13. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Nevada:* Carson City, August 6. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: Concord, Sept. 12-13. Sec., Dr. John Samuel Wheeler, Room 107 State House, Concord.

New Mexico:* Santa Fe, Oct. 8-9. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

North Carolina: *Reciprocity.* Morehead City, July 28. Sec., Dr. Joseph J. Combs, 419 Professional Bldg., Raleigh.

North Dakota: Grand Forks, July 4-7. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, December. *Reciprocity.* Columbus, Aug. 14. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Examination.* Portland, July 5-7. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July 10-13. Acting Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, Sept. 4. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

Rhode Island:* *Examination.* Providence, July 5-6. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: Rapid City, July 17-18. Sec., Dr. Clarence E. Sherwood, 109 Center St., West, Madison.

Utah: Salt Lake City, July 11-13. Asst. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Washington:* Seattle, July 16-18. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

West Virginia: Charleston, July 9-11. Sec. Dr. N. H. Dyer, Capitol Bldg., Charleston 5.

Wisconsin:* Milwaukee, July 10-12. Sec., Dr. C. A. Dawson, River Falls.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, August. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

District of Columbia: *Examination.* Washington, Oct. 22-23. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Iowa: *Examination.* Des Moines, July 10. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: Detroit and Ann Arbor, Oct. 12-13. *Examination.* Sec., Miss Eloise LeBeau, 501 W. Michigan Ave., Lansing 15.

Nebraska: *Examination.* Omaha, Oct. 2-3. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada: *Examination.* Reno, July 3. Sec., Mr. Frank Richardson, University of Nevada, Reno.

Oklahoma: Oklahoma City, Sept. 14. Sec., Dr. Frank C. Gallaher, 813 Braniff Bldg., Portland 4.

Oregon: *Examination.* Portland, Sept. 8 and Dec. 1. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

Rhode Island: *Examination.* Providence, August 8. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Tennessee: *Examination.* Memphis, July 5-6. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Texas: *Examination.* Austin, October. Chief Clerk, Mr. B. H. Kirk, 306 Nalle Bldg., Austin.

Washington: *Examination.* Seattle, July 11-12. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

---

* Basic Science Certificate required.

DEATHS

Emerson, Linn ⊕ Orange, N. J.; born in McDonough, N. Y., in 1873; Jefferson Medical College of Philadelphia, 1897; an Associate Fellow of the American Medical Association and in 1914-1915 a member of its House of Delegates; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; on the advisory board of Selective Service during World Wars I and II; at one time attending oculist at Manhattan Eye, Ear, and Throat Hospital in New York; consulting ophthalmologist to the New Jersey Orthopedic Hospital, House of the Good Shepherd, Dover (N. J.) General Hospital, and the Orange Memorial Hospital, where he died April 17, aged 77, of cerebral hemorrhage.

Hodges, Joe Shirley, Dallas, Texas; born in Canton, Texas, Sept. 23, 1897; Tulane University of Louisiana School of Medicine, New Orleans, 1923; clinical associate professor of pediatrics at Southwestern Medical School of the University of Texas; formerly on the faculty of Baylor University College of Medicine; member of the American Medical Association; a charter member of the Dallas Southern Clinical Society; in 1947 president of the Dallas Pediatric Society; president of the Highland Park school board; chairman of the management board that planned and built the Park Cities YMCA and president of the Southwestern Amateur Athletic Union; served as city health officer for University Park; affiliated with Parkland Hospital; died April 24, aged 53, of coronary occlusion.

Coonse, George Kenneth ⊕ Boston; born in Seattle Dec. 25, 1897; Harvard Medical School, Boston, 1924; certified by the National Board of Medical Examiners; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; associate in orthopedic surgery at his alma mater; affiliated with Boston City Hospital and the Newtown-Wellesley Hospital in Newton Lower Falls; at one time professor of orthopedic surgery at the University of Missouri in Columbia, where he had been consulting orthopedic surgeon at Boone County Hospital and chief surgeon of the Missouri State Crippled Children's Service; died Feb. 15, aged 53.

Salinger, Harry, Chicago; born in Chicago March 7, 1883; Jenner Medical College, Chicago, 1912; member of the American Medical Association; past president, vice president, and formerly director of the Bankers Association for Foreign Trade, a vice president and director of the Chicago Association of Commerce, a member of the foreign advisory committee of the University of Illinois, and a member of the executive committee of the foreign reconstruction committee of the National Foreign Trade Council; retired vice president of the First National Bank of Chicago; died in St. Luke's Hospital April 8, aged 68, of carcinoma of the liver.

Brown, Thomas Kenneth ⊕ St. Louis; born in Soldier's Grove, Wis., Dec. 17, 1898; Washington University School of Medicine, St. Louis, 1924; professor of clinical obstetrics and gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; member of the American Gynecological Society; served as president of the St. Louis Gynecological Society; chief-of-staff of Homer G. Phillips Hospital; affiliated with City, St. Louis Maternity, Barnes, and Children's hospitals; died in Rochester, Minn., April 30, aged 52, of coronary insufficiency.

Blandford, Mark Hardin, Columbus, Ga.; Baltimore Medical College, 1908; for many years city physician; on the staff of City Hospital, where he died April 6, aged 66, of diabetes mellitus.

Browning, Irving Robert, Grand Rapids, Mich.; Rush Medical College, Chicago, 1920; surgeon for the Pennsylvania Railroad Company; served during World War I; died in Butterworth Hospital April 29, aged 59, of coronary occlusion.

Buechler, Joseph L. A., Freeburg, Mo.; Barnes Medical College, St. Louis, 1893; physician for the Chicago, Rock Island & Pacific Railroad; died April 21, aged 77, of diabetes mellitus and heart disease.

Burriss, Walton Swindells, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1905; member of the American Medical Association; affiliated with St. Luke's and Children's Medical Center; died in Newton, Pa., April 23, aged 68, of coronary thrombosis.

Cabot, Caroline Whittier, Weehawken, N. J.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1887; died April 26, aged 96.

Cardell, Leonard Arthur, Nashville, Tenn.; Meharry Medical College, Nashville, 1929; died April 12, aged 47.

Clark, Samuel Ford, Ypsilanti, Mich.; Meharry Medical College, Nashville, Tenn., 1916; formerly county coroner; served during World War I; died April 19, aged 62.

Cohen, Rose, New York; Cornell University Medical College, New York, 1905; an Associate Fellow of the American Medical Association; died in April, aged 84, of arteriosclerosis.

Combs, John Wesley, Santa Ana, Calif.; Kentucky University Medical Department, Louisville, 1906; died in Santa Ana Community Hospital April 25, aged 75, of coronary thrombosis, chronic arthritis, abdominal aneurysm, and prostatic hypertrophy.

Conroy, John Stanislaus, Miami, Fla.; Jefferson Medical College of Philadelphia, 1910; served during World War I; died March 30, aged 63, of coronary artery disease.

Cox, Jonathan West, Powell, Tenn.; Wayne University College of Medicine, Detroit, 1943; served an internship and residency at Knoxville (Tenn.) General Hospital; county health officer; died March 23, aged 41, of heart disease.

Cragwall, Albert Owen, Stephenville, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; member of the American Medical Association; died May 18, aged 74, of heart disease.

Davison, Bruce Howard, Port Arthur, Texas; Baylor University College of Medicine, Dallas, 1920; member of the American Medical Association; died April 9, aged 54, of carcinoma of the pancreas and liver.

De Armond, Richard S., Portland, Ore.; Williamette University Medical Department, Salem, 1904; member of the American Medical Association; died April 20, aged 75, of cerebral hemorrhage.

Decker, John Jacob ⊕ Manhasset, L. I., N. Y.; New York University Medical College, New York, 1897; past president of the Bronx County Medical Society; served on the staff of the Harlem Eye and Ear Hospital in New York; died in Albany March 7, aged 77, of cerebral arteriosclerosis.

Donovan, Patrick M., Canandaigua, N. Y.; University of Buffalo School of Medicine, 1901; died April 30, aged 76.

Dugan, Lawrence Jay, Maplewood, Mo.; University of Arkansas School of Medicine, Little Rock, 1933; member of the American Medical Association and the American Association of Industrial Physicians and Surgeons; served during World War II; died in the Veterans Administration Hospital, Jefferson Barracks, April 25, aged 44, of cerebral thrombosis, hypertension, and cardiovascular disease.

⊕ Indicates Fellow of the American Medical Association.

Dulin, John Albert, Sigourney, Iowa; State University of Iowa College of Medicine, Iowa City, 1903; member of the American Medical Association; died in Mount Pleasant April 2, aged 76, of bronchopneumonia.

Ehlers, Henry ⊕ Fowler, Calif.; University of California Medical School, San Francisco, 1914; served during World War I; on the staff of Fowler Municipal Hospital, where he died April 25, aged 61, of cerebral hemorrhage.

Ellingson, Abel Rudolph ⊕ Detroit Lakes, Minn.; University of Minnesota Medical School, Minneapolis, 1925; fellow of the American College of Surgeons; past president of the Clay-Becker Counties Medical Society; for many years county coroner; served as a member of the city school board; on the staff of St. Mary's Hospital; died in St. Barnabas Hospital, Minneapolis, May 21, aged 54, of coronary thrombosis and cerebral embolism.

Epstein, Samuel S., Chicago; Chicago College of Medicine and Surgery, 1914; member of the American Medical Association; also an attorney; state representative of the 19th District; died in Mount Sinai Hospital April 21, aged 61, of coronary disease.

Eshleman, Robert H., Philadelphia; Medico-Chirurgical College of Philadelphia, 1911; member of the American Medical Association; died April 28, aged 64, of carcinoma.

Estes, Elmer Nelson, Lexington, Ky.; Louisville Medical College, 1906; member of the American Medical Association; on the courtesy staff of St. Joseph Hospital and Good Samaritan Hospital, where he died April 14, aged 68, of cerebral hemorrhage.

Faulkner, Coryell Vincent, Lake Worth, Fla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1899; served during the Spanish-American War; died in the Veterans Administration Hospital, Coral Gables, March 19, aged 78, of arteriosclerotic heart disease.

Fischbach, Howard Phillip, Sr. ⊕ Cincinnati; Pulte Medical College, Homeopathic, Cincinnati, 1909; fellow of the American College of Surgeons; on the staff of Bethesda Hospital; died in Flathead Lake, Mont., April 22, aged 66, of coronary thrombosis.

Fisher, John Baxter, Memphis, Tenn.; Memphis Hospital Medical College, 1901; died in the Baptist Hospital April 6, aged 76.

Fisher, Roy Alm, Jr., Knoxville, Tenn.; University of Tennessee College of Medicine, Memphis, 1939; member of the American Medical Association and Southeastern Surgical Congress; died in Fort Sanders Hospital April 29, aged 36, of Hodgkin's disease.

Gholson, Norman Glasgow, Holly Springs, Miss.; Medical College of Ohio, Cincinnati, 1904; died in Memphis April 8, aged 75.

Hall, Rosetta Sherwood, Ocean Grove, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1889; for many years a medical missionary in the Far East; died April 5, aged 85, of heart disease.

Hodskins, Morgan Brewster, Palmer, Mass.; University of Vermont College of Medicine, Burlington, 1899; member of the American Medical Association, American Psychiatric Association, and the New England Society of Psychiatry; specialist certified by the American Board of Psychiatry and Neurology; served with the Massachusetts Department of Mental Health; retired as superintendent of Monson State Hospital in 1946; died in Wing Memorial Hospital April 3, aged 76, of arteriosclerosis.

Horton, Barney Elliott, Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1900; member of the American Medical Association; died April 23, aged 77.

Hutcherson, Robert L., Delaplaine, Ark.; Memphis Hospital Medical College, 1903; member of the American Medical Association; died in St. Bernard's Hospital in Jonesboro, April 26, aged 83.

Jenifer, Daniel of St. Thomas ⊕ Towson, Md.; University of Maryland School of Medicine, Baltimore, 1904; served in France during World War I; examining physician for the police and fire departments of Baltimore County; for many years physician for the Maryland Training School for Boys; on the staff of Union Memorial Hospital in Baltimore; died April 30, aged 67, of myocardial infarction.

Kalloch, Herbert Franklin, Fort Fairfield, Maine; Bellevue Hospital Medical College, New York, 1898; member of the American Medical Association; served on the board of health for many years; instrumental in founding the Carnegie Library; died April 2, aged 82.

King, William Rufus, Gila, Ariz.; St. Louis University School of Medicine, 1909; served during World War I; died in the Southern Pacific Sanatorium in Tucson May 9, aged 65, of acute coronary occlusion.

Kistler, William Earl, Swarthmore, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1909; affiliated with J. Lewis Crozer Homeopathic Hospital, Chester; director of the Swarthmore National Bank; died April 24, aged 66, of aneurysm.

Kline, Ernest Hall, Nyack, N. Y.; Cornell University Medical College, New York, 1928; member of the American Medical Association; fellow of the American College of Surgeons; served during World War II; attending surgeon, Nyack Hospital; visiting surgeon, Rockland State Hospital in Orangeburg; consulting surgeon, Letchworth Village in Thiells; died April 18, aged 48.

Somers, Charles Irving ⊕ Crisfield, Md.; George Washington University School of Medicine, Washington, D. C., 1933; died in McCready Memorial Hospital April 13, aged 43, of angina pectoris.

Spencer, Frank Daniel ⊕ Salt Lake City; Columbia University College of Physicians and Surgeons, New York, 1918; fellow of the American College of Surgeons; medical director of the Pacific National Life Assurance Company; local surgeon, the Denver and Rio Grande and the Western Pacific railroads and Utah Fuel Company; affiliated with St. Mark's Hospital, where he died April 13, aged 60, of coronary occlusion.

Spencer, Wilbur F., Geneseo, Ill.; Chicago Homeopathic Medical College, 1888; member of the American Medical Association; died in Mound Park Hospital, St. Petersburg, Fla., April 6, aged 87, of cerebral thrombosis.

Stimpson, George Clyde, Poy Sippi, Wis.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1908; member of the American Medical Association; served during World War I; died April 20, aged 68, of coronary thrombosis.

Strauss, Simon ⊕ St. Petersburg, Fla.; University of the City of New York Medical Department, New York, 1891; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1893; an Associate Fellow of the American Medical Association; member of the Medical Society of the State of New York; formerly on the faculty of New York Polyclinic Medical School and Hospital; served during World War I; formerly on the staff of the Israel Zion Hospital in Brooklyn; died in the Veterans Administration Center, Bay Pines, April 7, aged 83, of arteriosclerotic heart disease.

Thomas, John M. ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1900; on the staff of Grant Hospital; formerly physician at the Ohio State Penitentiary; died April 8, aged 75, of coronary occlusion.

Weiksner, Francis Alexander, Worcester, Mass.; Middlesex College of Medicine and Surgery, Boston, 1930; retired police surgeon; member of the American Medical Association; died in St. Vincent Hospital April 10, aged 49, of diabetes mellitus and hypertensive cardiovascular disease.

Weiss, Solomon, Chicago; Loyola University School of Medicine, Chicago, 1922; member of the American Medical Association; served during World War I; died in Evangelical Hospital April 28, aged 58, of coronary occlusion and arteriosclerosis.

Whitehead, Lawther Jackson ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1916; associate professor of radiology at his alma mater; specialist certified by the American Board of Radiology; served on the staffs of the Westbrook Sanatorium, Johnston-Willis Hospital, and Tucker Hospital; died Feb. 26, aged 59, of heart failure and hemiplegia.

Whitehouse, Eugene Dizer, Newcastle, Maine; Harvard Medical School, Boston, 1905; member of the American Medical Association and the Massachusetts Medical Society; formerly practiced in Quincy, Mass., where he was on the staff of Quincy City Hospital; died March 28, aged 72.

GOVERNMENT SERVICES

ARMY

Residents Begin Training in Army Hospitals.—Seventy-three Army physicians have been selected by the professional education committee of the Surgeon General's office to enter residency training on July 1 under the graduate professional education program. The number of residents selected for entry into the professional training program this year is less than in previous years owing to the fact that the Army Medical Service has fulfilled its commitment to those officers whose training was interrupted to serve in Korea by permitting them to re-enter their residencies. However, the 73 new residents will bring the total number of Army residents in training to 284.

In the selection of this group most consideration was given to those regular Army officers who had completed at least two years of commissioned service subsequent to their internship, under a policy of the secretary of defense. Officers serving in all parts of the world were considered, and those selected who were serving overseas were returned to the United States in time to begin training on July 1.

Eighteen specialty fields are represented among the 73 residents. Training in each of these specialties carries full credit toward certification by an American specialty board. This training is conducted by military and civilian physicians who are eminently qualified in their specialty fields. The new residents will be assigned to the following four Army hospitals: Brooke, Fort Sam Houston, Texas; Fitzsimons, Denver; Letterman, San Francisco, and Walter Reed, Army Medical Center, Washington, D. C.

U. S. ATOMIC ENERGY COMMISSION

Radiation Hazards Will Not Delay Rescue.—Brig. Gen. James Cooney, radiation safety adviser to joint task force 3 stated June 13 that "our experience in recent test programs repeatedly has demonstrated that radiation hazards will not delay rescue and recovery work after an air burst of an atom bomb. There is no reason that every casualty cannot be removed and treated immediately without serious radiation hazard to rescuers.

"In the case of a high aerial burst of an atomic weapon, such as I think probably would be used, there would be no residual radiation. In a low air burst just above the ground's surface, the significant residual radiation would be confined to an area 300 to 400 yards in radius. No rescue work would be required in this area because it would be devastated. Rescuers would not be subject to injurious ionizing radiation in reaching survivors.

"Radiation safety surveys made after the tests in the immediate area of Eniwetok Atoll and neighboring inhabited atolls failed to reveal any contamination of a serious nature. Food and drinking water outside the destroyed area continued to be fit for consumption.

"The immediate radiation hazard from the air burst disappears after the first two minutes. Rescue, fire fighting and recovery work can begin immediately in any area where there is life, as in any major catastrophe caused by conventional air attacks, earthquakes or disasters on the scale of those at Texas City and Halifax."

AIR FORCE

New Research Director.—Dr. Alfred H. Lawton has assumed the duties of research director for the Air Force Medical Service. Since 1948 he has been research chief for the Research and Education Service in the Veterans Administration Department of Medicine and Surgery and assistant professor of clinical medicine at George Washington University School of Medicine, Washington, D. C. He was formerly dean of the school of medicine and professor of physiology and pharmacology at the University of North Dakota and assistant professor of physiology, pharmacology and medicine at the University of Arkansas Medical School.

PUBLIC HEALTH SERVICE

Report on Influenza.—Influenza in the United States during 1951 was prevalent in the northwestern, central, and western parts of the country, according to a preliminary report on the third year of operation of the Influenza Information Center at the National Institutes of Health. The disease was mild and nearly all isolations were identified as the A-prime type, closely resembling isolations made in 1950.

The Influenza Information Center is the terminal reporting point for the Influenza Study Program in the United States. Reports of influenza outbreaks and laboratory identifications are furnished simultaneously to the center and to the state health department concerned by a network of eight regional influenza laboratories and 50 coordinating laboratories especially skilled in the investigation of influenza and other virus diseases. The Influenza Study Program in the United States is under the general supervision of an advisory committee responsible to the Surgeons General of the Public Health Service, the Army, Navy and Air Force. It is part of the world-wide influenza study program of the World Health Organization.

The first isolation of influenza virus in the winter season in the United States was reported in Pittsburgh from a patient who became ill on Dec. 27, 1950. The virus was A-prime type, but there was no general increased prevalence of influenza throughout the United States; however, isolations of virus from sporadic cases were made in the New York State region and the Michigan region. In the third week of January a small localized sharp outbreak of influenzalike disease was reported in central Alabama, and influenza virus A-prime type was subsequently isolated from material collected at that time.

In the last week of January influenza appeared in Niagara Falls, N. Y., and also in an isolated community in northwest Maine but was not confirmed etiologically. Early in February the disease increased in incidence in Niagara Falls and appeared in Buffalo and subsequently appeared in other communities in upper New York State, where several strains were established, and in some communities in New England, particularly in the eastern part of Massachusetts. During this time it also appeared in Philadelphia, reaching a peak the last of February, and influenza A-prime was recovered. Acute outbreaks occurred in three hospitals in New York City in the last half of February, involving both patients and staff, from which influenza virus was isolated. Concurrently an unusual prevalence of influenzalike disease was noted locally about the city, and virus was recovered. In Cleveland and Chicago a mild form of clinical influenza was noted in unusual numbers, and influenza A-prime virus was isolated from some of the cases. On the West Coast and in Texas clinical influenza also appeared, and serologic and virus isolation indicated it was the general A group.

During March the incidence subsided generally throughout the United States and reached normal levels the latter part of the month. Military installations, particularly Fort Dix and Fort Monmouth, N. J., had reported an unusual amount during February. The disease was very mild with no increased mortality in the young adult age groups, though the mortality figures for all ages showed a slight rise in the latter part of February and early March over a three-year median.

To date reports of 79 isolations of influenza A-prime virus have been received from laboratories in the United States this season. There have also been two type A, one type B, and one type C (Francis) strains isolated. A total of 958 paired sera have shown significant antibody rises for the general influenza A group, and 22 paired sera have shown rises for type B.

The Indo-China Mission.—Dr. Bernard W. Rosenburgh, a Public Health Service officer, was scheduled to leave June 15 for Saigon, Indo-China, to serve as a public health administrator attached to the special technical and economic mission of the Economic Cooperation Administration. He becomes the seventh PHS officer to join the Indo-China mission established by ECA at the request of the Viet-Nam government in May, 1950. He brings to his new post some six years' experience with the Bureau of Indian Affairs of the U. S. Department of the Interior, where he has served as medical officer at various Indian reservations. Previously he was superintendent of the Bronx Maternity Hospital, Bronx, N. Y., and an intern in the Israel Zion Hospital, Brooklyn. Dr. Rosenburgh received his A.B. from Columbia in 1930 and his M.D. from the University of Vienna, Austria, in 1938. His tour of duty in Indo-China is expected to last two years.

Examination for Regular Medical Officers.—An examination for appointment of medical officers in the regular corps of the United States Public Health Service will be held Sept. 4 to 6 at a number of points throughout the United States. Applications must be received no later than Aug. 6. Appointments will be made in the grades of assistant surgeon, equivalent to the Navy rank of lieutenant (j. g.), and senior assistant surgeon, equivalent to lieutenant. In making assignments, consideration is given to the officer's preference, ability, and experience; however, all commissioned officers are subject to change of station and assignment as necessitated by the needs of the service. Appointments are permanent in nature and provide opportunities to qualified physicians for a life career in clinical medicine, research, and public health.

Entrance pay for an assistant surgeon with dependents is $5,686.56 per annum; for senior assistant surgeon with dependents, $6,546. These figures include the $1,200 annual additional pay received by medical officers as well as subsistence and rental allowance. Retirement pay after 30 years of service or at the age of 64 is three-fourths of the annual basic pay at the time of retirement.

Application forms may be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C. Attention: Division of Commissioned Officers.

Dr. Kety Appointed Scientific Director.—Dr. Seymour S. Kety of Philadelphia has been appointed scientific director for the joint research program of the Mental Health Institute and the Neurological Diseases and Blindness Institute of the National Institutes of Health. Dr. Kety comes to the Public Health Service from the University of Pennsylvania, where he has been professor of clinical physiology at the Graduate School of Medicine. In 1949 he received the Theobald Smith Award for Research in Medical Sciences given by the American Association for the Advancement of Science. The award cited his work on measurement of blood flow and oxygen consumption of the human brain. He has been special consultant in physiology to the United States Navy and the Air Force and serves on the scientific council of the National Heart Association and the research council of the United Cerebral Palsy Association. He is also on the editorial board of the *Journal of Pharmacology and Experimental Therapeutics.*

Mission in Burma.—Dr. James Whitman Agna, Cincinnati, and Dr. David Hyman Feldman, Chicago, two Public Health Service officers, were scheduled to leave for Rangoon June 19 to join the Specialized Technical and Economic Mission in Burma, which is administered by the Economic Cooperation Administration. They are expected to remain there two years.

The ECA mission, undertaken at the request of the Burmese government, has been in existence since October, 1950, with Dr. Leroy R. Allen of the Public Health Service as chief of its public health division. The medical personnel attached to the mission now numbers 15. Primary emphasis is placed on the organization of public health demonstration teams to help train personnel within the country in modern public health methods.

Institute of Arthritis and Metabolic Disease.—The new National Institute of Arthritis and Metabolic Disease will have the following three main divisions: laboratory research branch, clinical investigations branch, and extramural programs branch. The new Institute replaces the former Experimental Biology and Medicine Institute and was established in 1950 by Public Law 692 to provide expanded activities for research in the fields of arthritis, rheumatism, and the metabolic disorders. Of the three main divisions in the new Institute, only the laboratory research branch has been established. This was formed by the transfer of the four laboratories that comprised the former Experimental Biology and Medicine Institute. Under the reorganization, the following were advanced to new positions: Dr. James S. Hundley is chief of the laboratory of biochemistry and nutrition, and Dr. Lyndon F. Small is the chief of the laboratory of chemistry. The following continue as chiefs of their laboratories: Dr. Ralph D. Lillie, laboratory of pathology and pharmacology, and Dr. Paul A. Neal, laboratory of physical biology. Chiefs of the three divisions of the NIAMD have not been appointed as yet.

Personal.—Dr. Dale C. Cameron has been appointed chief of the cooperative health services branch of the Division of Industrial Hygiene, U. S. Public Health Service. Formerly assistant director of the National Institute of Mental Health, Dr. Cameron recently completed a one-year postgraduate course at Johns Hopkins University, where he was awarded the degree of master of public health. Prior to that, he served one year as consultant to the fact-finding staff of the Midcentury White House Conference on Children and Youth, assisting in the preparation of the health section of the fact-finding report. He is a native of Nebraska.

Dr. Jack C. Haldeman has been appointed chief of the Division of State Grants of the Public Health Service succeeding Dr. Estella Ford Warner, who has been assigned to a Point 4 mission in Beirut, Lebanon. Dr. Haldeman will administer the multimillion dollar program of grants-in-aid to states for the development of state, territorial, and local public health services and will also direct a program of technical and consultive services provided, on request, to state and territorial health authorities. Since 1948 Dr. Haldeman has been medical director of the Arctic Health Research Center in Anchorage, Alaska.

112 Interns Appointed.—Appointment of 112 senior medical students to rotating medical internships beginning July 1, 1951, has been announced by the Public Health Service. The students are from 29 states, the District of Columbia, and Puerto Rico. They will serve in the 11 Public Health Service hospitals approved for internships by the Council on Medical Education and Hospitals of the American Medical Association. Interns are selected from senior students who will graduate during the year from approved medical schools. They are appointed assistant surgeons in the reserve corps of the Public Health Service and called to duty July 1. As members of the corps, interns serve on an active duty status and enjoy all the rights and privileges of commissioned officers, except that they will not be entitled to the $100 a month incentive pay.

First Dyer Lecture.—George W. Beadle, Ph.D., chairman, division of biology, California Institute of Technology, gave the first R. E. Dyer Lecture at the National Naval Medical Center, Bethesda, Md., June 21 on "Genetic Control of Metabolism." Dr. Beadle is known for his work on biochemical genetics, particularly for his demonstration of the influence of genes on specific chemical reactions.

VETERANS ADMINISTRATION

Hospital News.—On June 1, 1951, Dr. Lewis R. Wolberg, assistant clinical professor of psychiatry, New York Medical College and Flower Hospital, conducted a seminar at the Veterans Administration Hospital, Northport, L. I., N. Y., on the techniques of hypnotic induction.

Personal.—Dr. Houghton W. Baxley, present manager of the Veterans Administration Hospital in Fort Benjamin Harrison, Ind., has been appointed manager of the Huntington, W. Va., VA Hospital, replacing Mr. Samuel R. Goodwin, who will retire at the end of June. Replacing Dr. Baxley at Fort Benjamin Harrison will be Dr. Clifton H. Smith, who will move from the VA Hospital in Atlanta. The Fort Benjamin Harrison Hospital is scheduled to close in early 1952, at which time Dr. Smith will become manager of a new VA Hospital then to be opened in Indianapolis.

FOREIGN LETTERS

LONDON

Health Service Finance.—In his annual report for 1949-1950, Sir Frank Tribe, Comptroller and Auditor General, complains of the delay by the Ministry of Health in conveying to hospital authorities comments made by the auditors which "suggested irregularity or inadequate control of expenditure" (*Brit. M. J.* supp., May 12, 1951). The Ministry explained that these delays were due to pressure of work and certain other difficulties and has arranged for their more prompt attention in the future. Sir Frank Tribe also found that some hospital authorities had not adjusted or had declined to adjust excessive salaries when requested by the Ministry to do so, while in other hospitals defects have been found in the arrangements for paying wages or salaries. The Ministry told the comptroller that it relied on departmental auditors to draw attention to defects of this kind, but it proposed to include the subject in a general financial circular to hospital authorities.

A number of hospitals were still found to be failing to maintain adequate store accounts and inventories, despite criticism on this point in the Auditor General's previous annual report. Some latitude must be allowed because of the shortage of staff. The Ministry has not yet been able to extend its powers of central purchase to goods in general use other than specialized equipment and some scarce or costly drugs. The accounts include receipts totaling some 6½ million dollars from accommodations used by private (fee-paying) patients. These patients should pay enough to cover their full cost of treatment, but the Auditor General found that the charges at some hospitals were less than they should be if based on current costs in 1949-1950. In January of this year, the Ministry informed him that the situation would be watched.

The pricing of prescriptions is also considerably in arrears, and substantial payments on account are made to the chemists pending final settlement. The Ministry's auditors also drew attention to payments made to ophthalmic medical practitioners for tests carried out at hospitals at which the practitioners were employed by the hospital boards under contract as part-time consultants. The Ministry informed the Auditor General that some of these payments have been recovered, that others are being investigated, and that administrative action had been taken to prevent recurrence of irregularities of this kind.

In the same supplement of the *British Medical Journal* (May 12), Dr. Bathurst Norman of Sudbury, Suffolk, states that the annual report of the council reveals some of the problems that have arisen from the centralization of administration in the Health Service. Detailed but remote financial control by the Ministry makes for financial irresponsibility at the periphery. A nationalized health service can succeed only if it is decentralized and if responsibility is allowed locally. This pertains to professional as well as to administrative aspects. Many members of medical staffs have noted along with very substantial benefits a perceptible decline in morale and in the sense of personal responsibility. On the professional side there is no liaison between the local group and headquarters. There is, therefore, no method by which the quality of work done can be assessed. He particularly decries the deprivation of hospital staffs of effective control in staff appointments. The necessity for self-help has been removed from local hospitals, and they are losing the will and capacity for helping themselves.

Cutting from Hippocrates' Tree.—A cutting from a gigantic oriental plane tree on the island of Cos, under whose branches Hippocrates is reputed to have taught his pupils and held his open-air clinic, was planted recently in the Council garden at B. M. A. House, Tavistock Square. The cutting had been brought to this country by Dr. G. Loverdos, a Greek physician. Similar cuttings had been planted in Paris, Rome, Berne and Madrid. The Greek ambassador in London, M. Leon Melas, expressed the hope that the tree might flourish as a symbol of the happy relations between Great Britain and Greece.

PARIS

First International Congress on Psychiatry.—This congress was held in Paris Sept. 18-27, 1950, under the honorary presidency of Professor Lhermitte and the presidency of Professor Delay. More than 2,000 persons, representing 47 nations, attended.

BRAIN FUNCTION STUDIES FOLLOWING LOBOTOMY AND TOPECTOMY

H. J. de Barahona Fernandes (Lisbon) discussed the development of psychosurgery, which has achieved spectacular results. Meyer (London) reviewed the results of 122 anatomic examinations in cases of prefrontal leukotomy. Granular or agranular areas constitute the only striking architectural difference in the lobe itself. The study showed that specific mental faculties cannot be related to well-defined regions of the granular frontal cortex but that there is a relation between the degree of alteration of personality and the damage sustained by prefrontal regions. No significant information has been obtained with respect to the pathology of functional psychosis. According to the author, the recurrence of symptoms of schizophrenic and affective psychosis, and of neurosis after almost complete isolation of the prefrontal cortex, and the persistence of schizophrenic symptoms despite total bilateral lobectomy of frontal lobes render doubtful the theories on specific location of the morbid processes of these psychoses.

Freeman (Washington) reported on his research, made in collaboration with Watts, that led to "precision leukotomy." According to a hypothesis, visceral conscience, personal conscience, social conscience, and moral conscience would depend on neuronic mechanisms of the frontal cortex. Even very anterior lobotomy diminishes the function of dreams and phantasy and the activity of the mind. When lobotomy is more posterior, the other functions of personality are more or less reduced. When affect has disappeared, prefrontal lobotomy is valueless.

MENTAL TEST METHODS AND CLINICAL PSYCHIATRY

Bleuler (Zuerich) believes that projective tests are indispensable in the study of repression in the child but that they constitute only one means among others in adults. The tests help one to discover what is healthy in the patient. R. Nyssen (Brussels) believes that psychiatric application of the tests requires great prudence, as they are still in the experimental stage. A. Guera (Madrid) studied the thematic apperception test. The selectivity of projective tests must be perfected before results are comparable with, for instance, those of efficiency tests.

INDICATIONS FOR SHOCK THERAPY

Fiomberti (Varese) noted that shock therapy may be useful in neurosis but is usually contraindicated in epilepsy. The opinion that insulin fixes the results of electroshock is in no way established. R. Dreszer (Poznan) studied the role of acetylcholine in the pathogenesis and treatment of schizophrenia. Acetylcholine acts less through its relatively weak convulsive effects than through autonomic changes. L. Meduna (Chicago) discussed carbon dioxide therapy. Sakel (New York), who introduced insulin therapy in 1927, gave a critical account of the successes and failures of the treatment. He stressed that insulin exerts a direct action on the central nervous system and can, therefore, be effective in schizophrenia. This partly explains the failure of other convulsants used without insulin in the treatment of this disease.

EVOLUTION AND PRESENT TREND OF PSYCHOANALYSIS

Mlle. Freud (London) discussed unfulfilled infantile desires. She advocated further study of the new concepts of pyschoanalysis by experiments on normal and deprived children. Levine (Cincinnati) explained the trend of psychoanalysis in America, its role in psychiatry and in general medicine. He also dealt with the problem of dependence, which, he says, is maintained by verbal intercourse in the classical methods of psychoanalysis and which present techniques endeavor to avoid. Alexander (Chicago) emphasized this point.

The items in these letters are contributed by regular correspondents in the various foreign countries.

BEHAVIOR DISORDERS IN CHILDREN

Professor Heuyer presented statistics on 4,187 subjects treated in his ward for 20 years or more. Social adaptation, evaluated on the basis of professional, familial and social behavior criteria, is good in 10% of cases, medium in 50%, poor in 12% and very poor in 9%. These results permit optimism with respect to the future of children with behavior disorders. Thibout (Amsterdam) proposed a structural analysis of personality with distinction made between the material factors and psychological factors. Krevelen (The Hague) studied the problems of the only child, Fortes (Lisbon) children's reactions to war memories, and Sunier (Amsterdam) the prognosis of children of psychotic parents.

GENETICS AND EUGENICS

Fraser Roberts (London) dealt with the genetics of feeblemindedness, Slater (London) with the genetic aspects of personality, and Penrose (London) modern methods in the study of human genetics. F. Kallmann (New York) studied 1,332 families with twins. A recessivity of schizophrenia and incomplete dominance of depressive mania were noted.

MISCELLANY

Other subjects discussed at the congress included psychopathology of delirium, disorders consecutive to war, depersonalization, endocrine and vitamin therapy in psychiatry, group psychotherapy and cybernetics.

Several films were presented, including one portraying the activities of the clinic of child neuropsychiatry of the Paris Faculty (Professor Heuyer), one on group therapy (Slavson, U.S.A.), and one on anxiety in the child (by Rene Spitz). Two important exhibits were organized, one on pathologic art, at the Sainte-Anne's Hospital (Paris), and the other on the history and progress of psychiatry, at the Palais de la Decouverte.

NORWAY

Discovery of Cancer of the Stomach by Mass Radiography.—The latest publication from the Norwegian Radium Hospital comes from Dr. Selmer Rennæs, who makes an urgent plea, in the organ of the Norwegian Medical Association (*Tidsskrift for Den Norske Laegeforening*), April 15, 1951, for the systematic radiographic examination of everyone over the age of 50. He cites the findings of two large Norwegian hospitals, where in recent times only 17% of the patients with cancer of the stomach underwent resection. The percentage of operable cases could be raised by the routine periodic examination of the feces for blood in persons of cancer age, but experience has shown that the public is unwilling to cooperate wholeheartedly in such a measure. On the other hand, systematic radiographic examinations are accepted quite willingly. According to the experience of the Radium Hospital, it is possible to examine some 30 to 50 persons hourly by this method at a cost of about kr.2 each (three radiograms).

The cost of such systematic radiographic examination for cancer of the stomach is evidently much higher in the United States than in Norway. As Dr. Rennæs points out, estimates in the United States show that it costs from $5,000 to $10,000 to discover a single case of cancer of the stomach by this method. These figures correspond to kr.35,000 to kr.70,000. On the other hand, if one case of cancer of the stomach can be found in Norway per 1,000 radiographic examinations of persons over the age of 50, the cost would be only between kr.2,000 and kr.3,000 for each positive case. The cost to the community of employing so many more radiologists for the execution of this measure would, of course, largely depend on the frequency with which it had to be repeated, and Dr. Rennæs points out that it should not be necessary to repeat the examination every three months as suggested in some quarters. As for the age limit, he would reserve this measure for persons over the age of 50, as statistics for 1926-1935 have shown that between the ages of 31 and 50 there were only six deaths from cancer of the stomach per 10,000 live males in Norway. However, for persons with hypochylia, achylia, or pernicious anemia—conditions accompanied by susceptibility to cancer of the stomach—the age limit should be some years below 50, and their radiographic examination should be repeated every year or half-year.

There remains one argument against this measure, and Dr. Rennæs admits that it is cogent. The sense of security conveyed by a negative radiographic report may be false. Römcke of the Drammen Hospital has shown that 56 out of 616 cases represented diagnostic mistakes referable to an ordinary radiographic examination. But no diagnostic test is foolproof, and, as long as other diagnostic methods are not ignored, this argument against a systematic search for cancer of the stomach by radiographic examinations should lose much of its force.

Unification and Control of Medical Certificates.—The Norwegian Medical Association has, through special committees, studied the problem of medical certificates for several years. The last committee issued a report on March 1, 1951. It is certain not to be the last word on the subject, but it gives a good bird's-eye view, and it will provide the basis for a permanent solution of this problem. There seems to be an almost indefinite variety of certificates to which a doctor is expected to put his name, and the possibilities of trouble for him are even more varied. He is blamed for (1) basing his certificates on inadequate examinations, (2) issuing certificates of so reserved or summary a character that they have little or no medical significance, or (3) betraying such great prejudice in favor of the person examined that the certificate is medically indefensible and incompatible with objective judgment.

Three main recommendations are presented in this report: 1. Rules should be laid down for the guidance of doctors with regard to their conduct in this matter. 2. A permanent body with a paid secretary should be created with a view to dealing with certificate problems as they arise. 3. The doctor's work in this field should be rationalized so that some uniformity in the drafting of certificates can replace the present confusion of forms. With regard to the second point, it is urged that the first duty of the proposed new body would be to raise the general medical standard in the matter of issuing medical certificates. This body should be composed of four members and four alternates. They should be appointed by the Norwegian Medical Association for a term of four years and should preferably be resident in or near Oslo, in order to be always on hand when required. The problem of how to remunerate doctors for this work will, perhaps, be simplified when rationalization and standardization have thrown further light on its scope.

Prenatal Prophylaxis of Congenital Syphilis.—Since 1943, the notifications of cases of congenital syphilis in Norway have numbered about 70 to 80 every year. This is assuredly an underestimate, because of the cases that escape detection for want of evidence of syphilis during the first few months of life. Again, syphilis is probably often overlooked when it leads to abortion and stillbirth. For many years the prenatal prophylaxis of congenital syphilis has hinged on arsenic and bismuth, whose efficacy was such that they were not promptly abandoned when treatment of syphilis with penicillin was introduced in 1943. At the dermatological department of the Rikshospital in Oslo, penicillin has been combined with arsenic and bismuth until it was clear that penicillin alone was reliable. Such an approach might not be attractive to many, but it has been supported by a report by Dr. T. Berdal published in *Tidsskrift for Den Norske Lægeforening*, April 1, 1951. His material consists of 45 syphilitic pregnant women, most of whom were given the combined treatment in the three-year period 1947-1949. With only one exception the infants born to these women were kept under clinical and serologic control for more than four months after birth, and in most cases for more than a year. Not one of the infants showed any sign of syphilis. The reaction of the women was equally satisfactory. They were kept under observation for eight to 42 months, and not one presented any evidence of clinical or serologic relapse at the last examination. In this series of cases, there were four women whose pregnancies ended in abortion or stillbirth, but in none of them could syphilis be held responsible.

Despite this achievement, combined treatment with penicillin, arsenic, and bismuth has now been replaced in Dr. Berdal's hospital by treatment with penicillin alone. The adoption of this policy is to a certain extent a tribute to the work of Mary S. Goodwin, whose report in 1950 on the treatment of more than 850 pregnant women treated in various ways with penicillin is singularly convincing. The treatment now adopted at Dr. Bersdal's hospital consists of injections of procaine penicillin G in oil and aluminum monostearate (2%). The total dose consists of six million units, the daily dose being 600,000 for 10 days. The 600,000 units may also be given every other day for 20 days. This treatment can be given at any time during pregnancy, but preferably before the eighth month.

Life Expectancy in Norway.—In April, the Norwegian Statistical Central Bureau issued a statement concerning its calculation of life expectancy in Norway in a prewar and a postwar period, the former covering the years 1931-1940 and the latter 1945-1948. Between these two periods, a remarkable increase in life expectancy can be recorded. For boys at birth it has risen by 3.7 years and for girls by 4.1 years. A man aged 50 has an increased life expectancy of 1.5 years; a man aged 60 has an increased life expectancy of 1.3 years. Even at the age of 70, for men the increase is 0.8 years. The mortality for women at the child-bearing age is now so much reduced between the ages of 15 and 45 that, among 100 women aged 15, as many as 94 would probably be still alive at the age of 45 years. As for males, among 100 aged 15, there should still be 74 alive at the age of 65. Only 69 of them would have been alive at this age according to the calculations based on the 1931-1940 period.

DENMARK

The Anesthesiology Center in Copenhagen.—The first course in anesthesiology in Copenhagen was completed on April 27, marking a very important event in the history of this subject. This course, which is being resumed early this summer, is organized by the faculty of medicine of the University of Copenhagen and the Danish ministry of health in cooperation with the World Health Organization (WHO). It is the first international course of its kind to be held in Europe, and its international character is emphasized by the considerable number of countries represented. The teachers come from the United States, England, and Sweden, and the students are from Austria, Denmark, Finland, Iceland, Jugoslavia, Norway, and Sweden. In the course beginning this summer, France, Greece, and Switzerland are also represented. On the teaching staff, the cooperation has been secured of surgeons, physicians, physiologists, psychiatrists, radiologists, pharmacologists, and pathologists.

In a leading article in the organ of the Danish Medical Association, *Ugeskrift for Laeger,* it is pointed out that this wide range of subjects, corresponding to the above list of specialists, shows what an all-embracing specialty anesthesiology has become since the days when the administration of a general anesthetic was a mere incident in the hospital life of a junior intern or nurse. Hospitals now are creating anesthesia appointments which are difficult to fill, for want of candidates possessing the qualifications now held essential for a specialist in this field. In the same number of *Ugeskrift for Laeger,* the leading article is written by a distinguished American, Dr. Ralph M. Waters, whose contribution to anesthesia is so important that the editor refers to him as the "grand old man" of anesthesiology.

Danish Cancer Statistics.—The centralization of cancer data in the Cancer Register, instituted only a few years ago, is now yielding valuable statistical information, which Dr. Johannes Clemmesen publishes from time to time. His latest report covers the years 1943-1947, inclusive. He gives the totals and the percentage incidence of malignant disease for each organ or group of organs for each sex. For example, there were 1,056 males with malignant disease of the buccal cavity and pharynx. These cases represented 5.16% of all the cases of malignant disease throughout the body in males. The corresponding percentage for females was only 1.59. Males were also in the majority with regard to the digestive tract and peritoneum, with 49.37% as compared with only 33.95% for females. Within this same area, malignant disease of the rectum made up 10.31% of the 49.37 for males, while the corresponding figure for females with cancer of the rectum was only 5.27%. Primary malignant disease of the lungs was far commoner in males than females, the percentages being 3.51 and 0.50, respectively. The incidence of breast cancer was 19.50% for females and only 0.26 for males. Malignant disease of the uterus was responsible for 16.67% of the female cases. The total incidence of malignant disease in the period under review shows males in the minority, with 20,477 cases as compared with 25,758 female cases.

AUSTRALIA

Contract Medical Practice Ceases.—For nearly a hundred years in Australia there has been in existence a form of contract medical practice known as "lodge" work. This was modeled on the "club" practice in Britain. Under this arrangement, members of "friendly societies" would pay a regular amount of about $10 per year and would receive various benefits, such as sick pay, free medicines, funeral benefit, and medical service. The contract would be made between the society and a general practitioner for medical attendance on the member, his wife, and children under 16 years of age at an annual fee of about $4. The medical attendance was little more than "advice and a prescription," and for anything more than this the patient would be sent to a public hospital. Concessional rates (extra to the contract) would be charged for obstetrics, surgery and anesthesia. The scheme worked reasonably well, and it did provide the young doctor with the nucleus of a practice and an assured though small income. Some doctors "specialized" throughout their life in this type of practice, having more than 1,500 families on their lists.

Now, however, this form of practice will cease. Lodge members will become private patients with full freedom of choice of doctor, and the lodge funds set aside for the purpose of providing medical service will be used to refund in part the fees paid to doctors by the member. The doctors will be prepared to make some concessions to such members, but the important principle of "fee-for-service" instead of contract has been established. Negotiations have reached finality in every state except Tasmania and Queensland, and these are expected to come into line with the rest of Australia.

One of the reasons for this situation is the rapid growth of medically organized prepayment schemes, which provide the part payment of a wide range of medical and hospital services. The largest of these organizations is the Medical Benefits Fund of Australia. The present government has announced its plans to subsidize those approved organizations that offer a wide scale of refund payments. The "friendly societies" did not offer a sufficiently wide refund service, and consequently they will cease to function in this way or else increase the scope of their medical benefits on a refund-of-fee basis.

Infection with Leptospira Pomona.—In the case of two diseases identified in Queensland, Q fever and infection with Leptospira pomona (Pomona fever), what was thought to be purely local diseases have now been shown to be worldwide. Q fever, caused by Rickettsia burneti, was originally identified by Derrick as the cause of a local outbreak among slaughterhouse workers in a Brisbane suburb. Now it has been reported from every country with laboratory facilities for investigation. Similarly, a new strain of leptospirosis was reported in Pomona, a small town of a thousand inhabitants a hundred miles north of Brisbane. The cases were few, they occurred only in wet weather and only in persons (mostly men) who were in daily contact with cows and pigs.

A similar infection has been observed in the Argentine and in the United States in humans, and recovery of the organism from horses with iridocyclitis has been reported. Also, the organism has been shown to be a cause of meningitis. In the original description of the syndrome of infection with Leptospira pomona, muscular pain was a constant feature; recent investigators in the United States report that muscle biopsy has shown characteristic histological features on the third day of infection, whereas agglutination reactions do not develop before about 12 days.

CORRESPONDENCE

TEACHING BY EXAMPLE

To the Editor:—The Army informed the Washington office of the American Medical Association that one out of an estimated 3,000 ASTP physicians with no active military service had volunteered for active duty by the end of August, 1950 (A. M. A. Capitol Clinic No. 34, Sept. 5, 1950). A reliable source of information indicates that by early April, 1951, only half the physicians in the United States in categories 1 and 2, registered last October under the professional men's draft law of September, 1950, had agreed to accept a commission and be available without protest for active duty in the armed forces. Such evidence of the lack of a feeling of a very personal, individual, and immediate sense of responsibility for the care of the members of the armed forces who protect us from ruthless aggressors is a matter of grave concern. This is over and above the annoyance of the method which must be used to get these physicians into active service.

We believe that the "Wait and see if I won't escape" attitude has been spawned in large part by the deferment policies promoted during World War II by faculty members of medical schools and by trustees, directors, and chiefs of services in teaching and nonteaching hospitals, and acquiesced to by draft boards and the armed forces. Medical students, hospital interns and residents, practicing physicians, and the general public need only the dimmest of vision to see the advantages—professional, personal, and monetary—accruing to many of those who stayed home. The editorial board of the *Norfolk Medical News* called attention to this ill-advised deferment policy in a letter to The Journal of April 17, 1943. We see many of the same weakling-breeding policies employed now.

The need for teaching by example is basic. We urge the following program, so that all, including the medical students, may see that the members of the medical profession share responsibilities, even if belatedly:

1. That the Department of Defense, each branch of the armed forces, the American Medical Association, state societies, medical schools, and hospitals join in urging a revision of the draft law, extending the age to 55 for physicians liable to service under it. The period of required active duty should be set at two years if the total strength of the armed forces be under five million, at three years if the total strength is over five million.

2. That the Department of Defense and each branch of the armed forces revise tables of organization to utilize more physicians of ages 45-55, and that physicians of this age group who have not served in World War I or II be placed soon on active duty, utilizing the older first. This will reduce the number of young physicians who may be required to serve for unduly prolonged terms or for more than one term of duty.

3. That medical schools, hospitals and clinics make immediate plans for releasing their physicians and that they draw up, publicize, and follow a system of rotation.

The example of deferment of "teachers" and "leaders" has led to a serious defect of thought in the profession. An example of sharing responsibility will help to correct this defect, which is far more serious than to be simply classified as "unfortunate" and allowed to continue. Prompt and vigorous revision of policy is necessary.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

NEW HOSPITALS REGISTERED

The following hospitals were registered by the Council on Medical Education and Hospitals of the American Medical Association at its meeting in Atlantic City, June 9, 1951:

U. S. Army Hospital, Camp Rucker, Ala.
Sumter County Hospital, York, Ala.
Desert Mission Hospital, Phoenix, Ariz.
Valley Hospital, Willcox, Ariz.
U. S. Army Hospital, Camp Chaffee, Ark.
Washington County Hospital, Fayetteville, Ark.
Randolph County Hospital, Pocahontas, Ark.
Rogers Memorial Hospital, Rogers, Ark.
U. S. Army Hospital, Camp Cooke, Calif.
U. S. Army Hospital, Camp Roberts, Calif.
Monrovia Hospital, Monrovia, Calif.
Del Puerto Hospital, Patterson, Calif.
U. S. Air Force Hospital, Travis Air Force Base, Calif.
Northeast Colorado Memorial Hospital, Haxtun, Colo.
Sedgwick County Memorial Hospital, Julesberg, Colo.
Pioneers Hospital, Meeker, Colo.
Everglades Memorial Hospital, Pahokee, Fla.
U. S. Army Hospital, Camp Gordon, Ga.
U. S. Army Hospital, Camp Stewart, Ga.
Ben Hill County Hospital, Fitzgerald, Ga.
St. Anthony General Hospital, St. Anthony, Idaho
Twin Falls Clinic Hospital, Twin Falls, Idaho
Monterey Convalescent Home, Unit 1, Chicago
Monterey Convalescent Home, Unit 2, Chicago
Whitehaven Acres, Glenview, Ill.
Community Memorial Hospital, Staunton, Ill.
U. S. Army Hospital, Camp Atterbury, Ind.
Sloss Hospital, Terre Haute, Ind.
Memorial Hospital, Arkansas City, Kan.
Neosho Memorial Hospital, Chanute, Kan.
Bob Wilson Memorial Grant County Hospital, Ulysses, Kan.
U. S. Army Hospital, Camp Breckinridge, Ky.
State Tuberculosis Sanatorium, Paris, Ky.
U. S. Army Hospital, Camp Polk, La.
Curtis Clinic and Hospital, Mansfield, La.
Hargrove Clinic and Hospital, Oakdale, La.
Sabine Clinic and Hospital, Zwolle, La.
Utterback's Private Hosp., Bangor, Maine
Notre Dame Hospital, Biddeford, Maine
Deer's Head State Hospital, Salisbury, Maine
Athol Memorial Hospital, Athol, Mass.
U. S. Army Hospital, Falmouth, Mass.
U. S. Army Hospital, Fort Devens, Mass.
Bon Secours Hospital, Methuen, Mass.
Student Hospital, Ann Arbor, Mich.
Kirwood General Hospital, Detroit, Mich.
Lakeside General Hospital, Detroit, Mich.
U. S. Army Hospital, Fort Custer, Mich.
Midland King's Daughters' Home Hospital, Midland, Mich.
Glen Eden Hospital, Warren, Mich.
Lakefield Municipal Hospital, Lakefield, Minn.
Pioneers' Infirmary, Virginia, Minn.
Dr. Henry Schmidt Memorial Hospital, Westbrook, Minn.
Humphreys County Memorial Hospital, Benzoni, Miss.
District Two Community Hospital, Durant, Miss.
Tunica County Hospital, Tunica, Miss.
Stephens College Infirmary, Columbia, Mo.
U. S. Army Hospital, Fort Leonard Wood, Mo.
Lexington Memorial Hospital, Lexington, Mo.
Veterans Admin.. Hospital, Manchester, N. H.
Pinehaven Nursing Home and Hospital, Pinewald, N. J.
Memorial General Hospital, Las Cruces, N. Mex.
Francis Delafield Hospital, New York City
Madison Avenue Hospital, New York City
Central Suffolk Hospital, Riverhead, N. Y.
Rhinehart Memorial Hospital, Silver Creek, N. Y.
Alamance County Hospital, Burlington, N. C.
Alexander County Hospital, Taylorsville, N. C.
Our Lady of Mercy Hospital, Coldwater, Ohio
Ohio Tuberculosis Hospital, Columbus, Ohio
U. S. Air Force Hospital, Dayton, Ohio
Glencliff Hospital, Euclid, Ohio
Cottage Grove Hospital, Cottage Grove, Ore.
Myrtle Creek Hospital, Myrtle Creek, Ore.
Douglas Community Hospital, Roseburg, Ore.
Community Bailey Hospital, Chamberlain, S. D.
Little Creek Sanit. and Hospital, Concord, Tenn.
Cookeville General Hospital, Cookeville, Tenn.
Alexian Brothers Mountain Resort, Signal Mountain, Tenn.
Shackelford County Memorial Hospital, Albany, Texas
Student Health Center, Austin, Texas
Stephens County Hospital, Breckenridge, Texas
Jones Children's Haven, Dallas, Texas
Flow Memorial Hospital, Denton, Texas
Dilley Clinic Hospital, Dilley, Texas
City Hospital, Hemphill, Texas
Goodnight Hospital and Clinic, Lubbock, Texas
Madison County Hospital, Madisonville, Texas

Midland Memorial Hospital, Midland, Texas
Beaver County Hospital, Milford, Utah
U. S. Army Hospital, Camp Pickett, Va.
U. S. Army Hospital, Fort Worden, Wash.
Monroe General Hospital, Monroe, Wash.
Veterans Admin. Hospital, Seattle, Wash.
Veterans Admin. Hospital, Beckley, W. Va.
Veterans Admin. Hospital, Clarksburg, W. Va.
U. S. Army Hospital, Camp McCoy, Wis.
Crandon Emergency and Maternity Hospital, Crandon, Wis.
Holy Family Hospital, New Richmond, Wis.
Policlinica Sanchez Castano, Vega Baja, P. R.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Compensation of Physicians: Parent's Liability for Services Rendered to Children.—The plaintiff physician filed suit for the reasonable value of professional services rendered to the minor children of the defendant following a collision between a railroad train and an automobile in which the children were riding. From a judgment in favor of the physician, the defendant appealed to the Supreme Court of Nebraska.

The plaintiff alleged that he was a licensed physician and surgeon of Omaha, that he rendered medical and surgical services consisting of emergency treatment and subsequent care to three minor children of the defendant after they were injured in a collision between an automobile and a train, that the services performed and the care and treatment furnished them were "necessaries" and were performed and furnished with the knowledge and consent of the defendant and that the reasonable value of such services was the amount stated in the plaintiff's complaint. The answer of the defendant was a denial. The defendant strenuously contended that the omission of the trial court to instruct the jury as to the distinction between emergency treatment and treatment after the emergency had past was prejudicial error, and that the evidence in this case limits any recovery by the plaintiff to the amount of the reasonable compensation for emergency treatment furnished to the injured minor children.

It is conceded that the plaintiff physician performed medical and surgical services for the children of the defendant. Defendant and his wife were at the Clarkson Hospital at the time the children entered it and frequently thereafter until the children were taken from it. They met the plaintiff there, knew he had rendered and was rendering the services claimed by him for their children, and were in consultations with him and other doctors concerning the children and their care. They asked the plaintiff to secure the assistance of other doctors and to consult with them, and he did. The plaintiff also consulted with Dr. Barry, defendant's family physician, and called to his assistance Dr. Best when he first got on the case because of the emergency and the fact that he could not attend the three children at one time. The plaintiff and the parents of the children talked frequently about what was being done for them and discussed the possibilities of future developments. The defendant at no time communicated with the plaintiff that his services were not wanted or that he should discontinue his care of the children. More than a month after the services of the plaintiff were completed, he received a letter from the defendant in which defendant said "I deeply appreciate what you did when these accident victims were brought into the hospital and subsequently. . . ." The period during which the plaintiff rendered services for which compensation is claimed commenced on Aug. 11, 1946 and ended on Aug. 29, 1946. On the last date the physician plaintiff sent a statement therefor to the defendant. Defendant's reply to the plaintiff, more than a month later, bearing date of Oct. 7, 1946, stated: "I am acknowledging receipt of your letter of Aug. 29, 1946, in which you enclose your bill for professional services in connection with the four persons injured in the unfortunate accident at 76th and Dodge streets on Aug. 11, 1946. While I deeply appreciate what you did when these accident victims were brought into the hospital and subsequently, I was rather shocked by the amount of this bill, which I believe to be quite excessive. When the patients have made further progress toward recovery I shall avail myself of the first opportunity to discuss the matter with you." This at least, said the court, was an implied admission by the defendant of liability to the plaintiff for some amount for services furnished by him to "the four persons injured in the unfortunate accident . . . on Aug. 11, 1946." A finding of a jury based thereon that it was an express admission of liability would not be without evidentiary support. These statements by defendant after opportunity for knowledge of all the facts, deliberation, and mature conclusion, were in direct conflict with the denial in his answer and his testimony. A declaration by a litigant against interest relevant to a matter in issue and inconsistent with what is alleged or testified to by him is proper and generally important original evidence.

The defendant also complained that the trial court failed to instruct the jury on his theory of the case because it refused to advise the jury that the plaintiff could not recover from the defendant for the medical services involved if they were rendered in his capacity as surgeon of the Chicago and Northwestern Railway Company, were part of his regular duties as such surgeon, and included in the salary he received from the railway company. The tendered instruction was that if the jury found by a preponderance of the evidence that the plaintiff was employed by the railway company to treat the defendant's children, he could not recover against the defendant. The evidence is that at the time important to this controversy the plaintiff was engaged by the Chicago and North Western Railway Company as division surgeon for it and its subsidiary, Chicago, St. Paul, Minneapolis and Omaha Railway, on a salary to care for, when he was available, injured employees and passengers who received injury in transit on the lines of these companies. The plaintiff received nothing from the companies, or either of them, or from anyone for the services rendered the children of the defendant. There is no evidence that anyone in any way connected with either of the companies communicated with the plaintiff concerning the injuries to or the services rendered the victims of the accident which resulted from a collision of the auto in which they were riding and a train of the Chicago and North Western Railway Company. The trial court properly refrained from charging the jury as requested.

Other contentions of the defendant were also overruled and, on the basis of all the evidence, the judgment of the district court in favor of the plaintiff physician was accordingly affirmed. —*Brown v. Hyslop, 45 N.W. (2d) 743 (Nebraska 1951).*

MEDICAL MOTION PICTURES

Let's Have Fewer Colds: 16 mm., color, sound, showing time 10 min. Produced in 1950 by Coronet Films with the technical advice of Fred V. Hein, Ph.D., and Donald A. Dukelow, M.D., Bureau of Health Education, American Medical Association. Procurable on purchase from Coronet Films, 65 E. South Water St., Chicago 1, or on rental from Ideal Pictures Corp., 58 E. South Water St., Chicago 1.

This film points out to children and their parents the simple practices that can substantially reduce the number of colds children get each year. It explains the importance of avoiding contact with persons who have colds, avoiding chilling or overheating, and establishing good health habits. The scientific basis of the film is sound and is in accordance with present day knowledge of the transmission and treatment of colds. It is presented on a level that is understandable and convincing to children. Furthermore, it fills an important need in that it can be used for the instruction of parents. The animated sequences illustrating the physiology of the nose and throat would probably not be understood by children of elementary school age. They can be further criticized on the basis of being so oversimplified that they lose essential detail and, thus, their value for adults. The film is recommended for use in the elementary grades and may also be advantageously used with parent-teacher groups in order to elicit the cooperation of parents in training their children. The photography and sound are excellent.

Triethylene Melamine in Neoplastic Diseases.—Triethylene melamine (TEM) was administered intravenously in a dose of 2 to 3 mg. daily to patients with Hodgkin's disease, lymphosarcoma, and chronic lymphatic and myelogenous leukemia. The total dose for adults was 5 to 20 mg. Temporary improvement, similar to that effected by the nitrogen mustards, resulted. Triethylene melamine, in therapeutic doses, in contrast to the nitrogen mustards, rarely causes nausea, vomiting, or venous thrombosis at the site of injury. A limiting factor in therapy is that both triethylene melamine and methyl-*bis* (2-chloroethyl) amine are injurious to normal hemopoietic function. Careful regulation of the dosage is essential, so that prolonged or fatal depression of the bone marrow will be prevented. Triethylene melamine was also given orally to 58 patients with the above diseases and with mycosis fungoides. The course of treatment usually consisted of 20 to 40 mg., given in a three to five week period. This dosage varied greatly and was modified according to the diagnosis and the general condition and hematological state of the patient. Oral therapy produced no symptoms in 21 patients, slight nausea with vomiting in 33, and severe vomiting in two patients. Temporary periods of clinical improvement were effected in the diseases mentioned, but the results in patients with miscellaneous types of carcinoma were poor. The indications for the use of triethylene melamine are similar to those established for nitrogen mustard.

Coccidioidomycosis and Pulmonary Cavitation.—Studies were made of 92 patients with residual coccidioidal cavities, over half of whom were followed five years or longer. The cavities closed spontaneously in 25% of the group of 92 patients; they persisted for years without harm in 10%; they filled and formed nodules resembling neoplastic foci in 6%, and they ruptured and produced spontaneous pneumothorax in 2%. Approximately one-third of the patients with cavities required treatment by simple pulmonary collapse measures, such as pneumothorax or pneumoperitoneum, because of excessive bleeding or the increasing size of the cavity. These collapse measures were effective in 18 instances and failed in 10. Some of the smaller cavities, with roentgenographic evidence of fairly thick or firm walls, were removed from the lung by simple excision. Larger cavities required more extensive procedures, such as lobectomy or pneumonectomy. There was neither dissemination of disease from a residual pulmonary cavity nor any evidence of transmission of the infection from one person to another during more than 10 years of study of coccidioidal disease in the San Joaquin Valley. The author stresses the importance of recognizing the residual pulmonary changes following primary coccidioidomycosis and differentiating them from the lesions of pulmonary tuberculosis and neoplastic disease.

Scleroderma Treated with Cortisone.—Cortisone was used in the treatment of a patient with diffuse scleroderma involving the skin, the lungs, and the esophagus. The disease prior to cortisone therapy had steadily progressed in spite of several therapeutic attempts. With cortisone therapy the skin became softer and more pliable but did not return to normal; the motion of the hands was significantly improved; there was decided improvement of the esophageal peristalsis and some decrease of the dilatation, swallowing became almost normal, and the patient's mental attitude improved. There was no demonstrable change in the pulmonary involvement, although the cough disappeared. Of the side effects of cortisone therapy, rounding of the face, acne, and water retention were pronounced in the patient. After treatment the skin biopsy specimen showed progressive loosening of the collagen bands and an increased waviness, approaching the normal pattern. There was no significant change in the vascular picture, and changes in the elastic pattern could be accounted for by the contiguous change in the collagen. Cortisone therapy does not affect the fundamental course of scleroderma; however, it alters the characteristic collagen pattern of the disease.

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

taffin cells into this area, and the rather rare ganglioneuroma, which arises from Meissner's and Auerbach's plexuses. "Neuroappendicopathy" is a distinct clinical entity. It usually produces a dull ache or discomfort in the right lower quadrant, with slight tenderness at McBurney's point. Nausea with or without vomiting may be present. The condition can produce extremely severe pain, with acute tenderness and abdominal muscle spasm. Despite the apparent acuteness of symptoms and signs, the temperature is usually normal and the total white and differential blood cell counts tend to remain at normal levels. Careful questioning most often reveals a history of previous attacks. Of the 52 reviewed cases of the syndrome, 30 occurred in women and 22 in men. Ninety per cent of the patients fell in the age group 20 to 50. In 24 cases the diagnosis was established by the use of multiple sections of the removed appendixes and the Masson trichrome stain, while 28 were diagnosed by routine hematoxylin and eosin preparation. Before an appendix is considered normal in a patient with symptoms referable to the appendix, multiple sections stained with the Masson trichrome technique should be examined. As the diagnosis becomes commoner pathologically, ability to evaluate the clinical symptomatology of the condition will increase.

Studies on 5-Aminoacridine Hydrochloride.—The in vitro effectiveness of 5-aminoacridine hydrochloride on exudates from fulminating peritonitis induced in dogs by ligation and splitting of the appendix was compared with that of streptomycin, penicillin, sulfadiazine, and various combinations of these drugs. In the concentrations used, 5-aminoacridine hydrochloride proved at least as effective as penicillin, streptomycin, or sulfadiazine. Furthermore, its effectiveness appeared to be more consistent. There were only slight indications of a synergistic or additive effect of this drug. In most cases, when it was used in combination the effect was no better than when it was used alone.

Coronary Artery Disease of Long Duration.—Studies were made of 115 men and nine women who had been under observation for coronary artery disease for at least 10 yr. The average duration of cardiac symptoms was 13.6 yr. The age at the onset of symptoms had no apparent affect on survival or on the course of the disease. Patients whose illness began with simple angina pectoris had a better prognosis than those in whom it was initiated by a myocardial infarct. In 15 patients who had never had hypertension cardiac enlargement developed. Eighty-one patients (65%) were without cardiac symptoms for one or more years, and 89 (72%) followed their usual occupations during most of their illness. The unpredictable, variegated course of coronary artery disease and the frequent modifications of symptomatology in patients with this disorder are emphasized.

Myocardial Infarction with Rupture of Ventricle.—The occurrence of acute myocardial infarction with rupture of the ventricle in six patients between the ages of 68 and 76 has been reported. Four of the patients were women. The consensus of the literature places the incidence of rupture following acute myocardial infarction at approximately 9%. It occurred most frequently between the ages of 65 and 75. The myocardium is at its weakest during the first four days and is likeliest to rupture during this time. Rupture occurred in four of the author's patients within the first three days. That rupture occurred nine to 12 days after the infarction in the remaining two patients supports the general consensus that rupture may occur within two to three weeks after infarction. Necropsy revealed that in each case the site of rupture was through an infarction, the involved area being in the anterior wall of the left ventricle in four patients and in the posterior wall in two patients. The "blowout" type of rupture, in which the laceration was sharp and clean, was seen only in one case. The "dissection type," in which the laceration was ragged and associated with necrosis, undermining, and dissection of the myocardium for as long a distance as 2 cm., was observed in five cases. The main factors in the mechanism of rupture were the location of the infarct; the type of disease found at the site of rupture; high intracardiac pressure due to persistent hypertension, especially diastolic hypertension, after the initial shock of infarction; undue physical and emotional strain, and progressive heart failure. The best treatment for rupture of the heart lies in its prevention by adequate treatment of the acute infarction.

Intermittent Streptomycin Therapy.—Observations were made on 97 patients with pulmonary tuberculosis (61 far and 36 moderately advanced). Forty-nine of the patients received 2 gm. of streptomycin in four divided doses every third day; 48 received 1 gm. in two divided doses every third day. A course of streptomycin therapy lasted from 126 to 189 days, depending on response to therapy, time of sputum conversion to negative, and results of serial streptomycin sensitivity studies. The patients were maintained on strict bedrest before, during, and after treatment. In addition, cod liver oil, multivitamin preparations, and 300 mg. of ascorbic acid were administered daily. Fever, sputum quantity, and cough usually improved most rapidly during the first 42 days of therapy. After the 42d day, the status of most patients (75.3%) continued to improve; in 6.2%, improvement was followed by relapse, and in 18.5% no remarkable improvement was ever noted. Patients with widespread, chronic disease and, to a lesser extent, with bacterial resistance, showed poor clinical response. Tuberculous complications responded well to intermittent streptomycin therapy, and decrease in cavitary size was effected. The incidence of streptomycin toxicity is greatly reduced by regimens of intermittent therapy. It was 1.03% and 5.0% at the completion of 126 and 189 day courses of intermittent streptomycin therapy, respectively. The use of intermittent regimens delayed the emergence of streptomycin-resistant strains of Mycobacterium tuberculosis. The conversion rate in the present study was appreciably greater than that observed on previously used daily dosage schedules of similar duration. In the entire group of 97 patients, 37 (38.1%) had sputum conversion after 126 days of therapy. The emergence to predominance of drug-resistant tubercle bacilli appeared to be most frequently associated with far advanced, cavitary, and old disease.

Combined Streptomycin and Paraaminosalicylic Acid.—A comparative study of four dosage schedules in 283 patients was carried out at the United States Army Tuberculosis Center, Fitzsimons Army Hospital, during the past four years. In each schedule the patients were treated for 120 days. The four groups consisted of 66 patients who received streptomycin, 1 or 2 gm. daily; 25 who received paraaminosalicylic acid, 12 gm. daily; 97 who received streptomycin intermittently, 1 or 2 gm. every third day, and 95 who were treated on a combined regimen of streptomycin, 1 to 2 gm. every third day, concomitantly with paraaminosalicylic acid, 12 gm. daily. The patients on each regimen were similar with respect to age, sex, race, and duration, extent, and type of disease. All patients had moderately or far advanced pulmonary tuberculosis and had received no prior antituberculous drug therapy. Clinical, roentgenographic, bacteriologic, and drug toxicity factors were evaluated after 120 days of treatment. Clinical response, in terms of reduction of fever, reduction of sputum volume, and weight gain, was equivalent on all four regimens. Of patients with roentgenographic evidence of cavitation when therapy started, the cavities disappeared in not more than 20.5% after 120 days of therapy. The best results and the highest incidence of sputum conversion were obtained with the combined intermittent regimen (streptomycin every third day, paraaminosalicylic acid daily). No instances of bacterial resistance occurred with this regimen, compared with 75.9% after daily streptomycin, 33.3% after daily paraaminosalicylic acid and 33.3% after intermittent streptomycin regimens. The high incidence of toxic reactions (57.5%) that resulted when streptomycin was given daily decreased to 5% when the drug was given every third day for a similar period. The incidence of toxicity when paraaminosalicylic acid was given daily was also 5%. The higher incidence of toxic reactions (13.1%) that resulted when the two drugs were given together was not sufficient reason to discontinue the regimen except in four instances. Results were evaluated 60 days after the 120 day courses of therapy, because in this period it was frequently necessary to supplement the prior treatment with retreatment (drug therapy) or operative procedures. Clinical relapse was approximately equal (15.1 to 22.2%) on each of the regimens. Roentgenographic relapse varied from 0% in the daily paraaminosalicyclic acid group to 14.8% in the daily streptomycin group. Bacteriologic relapse ranged from 5.5% in the daily paraaminosalicylic acid series to 31.2% in the combined intermittent regimen. A loss of bacterial resistance to one or the other of the drugs was observed; this was pronounced in the daily paraaminosalicylic acid regimen and indicates that resistance may be less permanent to this agent than to streptomycin. The regimen of choice for periods up to four months when specific drug therapy is indicated for the treatment of nonmiliary pulmonary tuberculosis is a combined intermittent regimen of streptomycin administered every third day and paraaminosalicylic acid daily.

Treatment of Circumscribed Intrathoracic Lesions.—Harrington states that when routine roentgenoscopy reveals a circumscribed intrathoracic tumor and when a clinical diagnosis cannot be established by other diagnostic methods, exploratory thoracotomy is indicated, even in the absence of symptoms. This is justified because of possible malignancy or metastasis or of eventual compression of vital structures by an expanding growth, either malignant or benign. The risk of the operation is slight because of improved techniques of surgery and of preoperative and postoperative care. In a series of 291 patients operated on by the author for various types of benign or malignant extrapulmonary and intrapulmonary circumscribed lesions (including neuroblastomas, teratomas, thymomas, coelomic cysts, endotheliomas, carcinomas of the lung, metastatic tumors, mixed tumors, hamartomas, and granulomas), 52 of the lesions were asymptomatic and 12 of these were malignant. In nine of these 12 cases the malignant process was discovered early and removed completely. In addition, the 40 benign, symptomless lesions were removed before they had caused irreparable damage to surrounding structures or had undergone malignant change.

Resection of Auricular Appendages.—The majority of peripheral emboli in patients with rheumatic heart disease and persistent auricular fibrillation originate in the auricular appendages. For this reason resection of the auricular appendages has been suggested as a means of preventing recurrent arterial embolism in such cases. This operation was performed by Longmire and associates on three patients. Two patients with peripheral embolism had left auricular appendectomy and one with pulmonary embolism had right auricular appendectomy. Mural thrombi were demonstrated in each case. Cardiac function and electrocardiograms were not apparently influenced by the operative procedure. No evidence of further embolization was noted during a follow-up period of five to 10 months.

Uptake of Radioactive Iodine After Intravenous Administration. —Tracer doses of 40 to 100 μc of radioactive iodine in 5 or 10 cc. of isotonic sodium chloride solution were administered intravenously to 30 adult patients, 18 with clinically unmistakable, untreated hyperthyroidism, eight with a clinical diagnosis of nontoxic goiter, three with a clinical diagnosis of probable hyperthyroidism, and one with classic myxedema. Radioactive iodine was also given to a control group of 19 adults, who were considered to be clinically euthyroid. The thyroid uptake one hour after the tracer dose correlated satisfactorily with the activity of the thyroid gland and with clinical toxicity, permitting differentiation between euthyroid and hyperthyroid states. The method also offers advantages over the 24 hour oral method in rapidity and in diagnostic accuracy by reducing the overlap in values between normal and hyperthyroid persons.

Late Results with Methylthiouracil in Thyrotoxicosis.—Methylthiouracil was given to 220 women and 24 men with thyrotoxicosis for an average of one year. The initial dose of the drug was 250 mg. three times daily, usually given for one or two months. When the basal metabolic rate was restored to a nearly normal level, the dose was reduced to 250 mg. once a day and treatment with this dose was continued for two to four months. The final maintenance dose was 125 mg. two or three times a week usually for six months. Nine patients died during the observation period from intercurrent causes not related to the thyrotoxicosis. Treatment was discontinued in 44 patients for various reasons and in 25 of these for hypersensitivity, but no instance of agranulocytosis was observed. Eighteen of these 25 patients continued treatment with propylthiouracil. Treatment with methylthiouracil was concluded in 169 patients, 144 of whom continued without any treatment for six months or more and were followed up for six to 63 months (average, 32.9 months). Of these 144 patients, 87% made a complete recovery and 18% were improved but showed some persistent symptoms. On reexamination the goiter was, on the whole, smaller than before treatment. Exophthalmos was present in 7% of the patients at the time of reexamination as compared with 31% before treatment. Twenty-one patients had auricular fibrillation before treatment as compared with six at the time of reexamination. True recurrences occurred in 21 of these 144 patients (14.6%) after a symptom-free period of six to 45 months. The actual frequency of recurrence was higher (20.7%), because in 18 additional patients the treatment was repeated only because of recurrence and was not yet concluded at the time of the reexamination. On the average, the recurrences were mild and the patients could soon be given a small maintenance dose. The final results in the recurrent cases were as satisfactory as those obtained in the nonrecurrent cases. The incidence of recurrence was much higher among the patients with nodular goiter than in those with toxic diffuse goiter, in whom it was only 11.9%. Therapeutic results in the patients with toxic nodular goiter also were much poorer than in those with toxic diffuse goiter. Patients with toxic nodular goiter should be primarily advised to submit to surgical treatment.

Reestablishing Lymph Drainage in Lymphedema.—Zieman describes a simple, nonmutilating method of reestablishing lymph drainage in an extremity subject to lymphedema. It consists of subcutaneous implanting of one or more lengths of nonabsorbable suture longitudinally along the extremity and across the region of lymphatic obstruction. This in effect creates a new channel through which lymph can drain. The suture (no. 1 nylon) is introduced through the bore of a no. 19 or no. 20 gage needle 17.7 to 30.4 cm. in length that has previously been inserted subcutaneously along the desired path. The needle is withdrawn, and the suture is left in place. The ends of the suture are cut so that they retract 0.6 cm. under the surface of the skin. Following the implantation, the extremity is elevated and wrapped with an elastic bandage. The author has used the method in lymphedema of the arm following radical mastectomy, lymphedema of the leg due to invasion of the inguinal nodes by a Hodgkins infiltrate, and lymphedema of the penis and scrotum. He reports rapid and painless reduction in the size of the affected member.

Carcinoma of Gallbladder and Bile Ducts.—Carcinoma of the gallbladder constitutes about 3% of all malignancies, and carcinoma of the bile ducts, about 3½%. In women carcinoma of the gallbladder may constitute 8 to 10% of all malignancies. Both types of carcinoma tend to occur in the older age groups. Adenocarcinoma is the commonest pathological type. It may be papillomatous or diffusely infiltrating in form. Mucus-producing and squamous carcinoma also occur. Gallstones are found in 80 to 100% of cases of gallbladder carcinoma and in a somewhat lesser percentage of cases of duct carcinoma. From 4 to 5% of patients with gallstones eventually have carcinoma of the gallbladder. The clinical picture of carcinoma of the gallbladder and ducts is extremely variable, and the patient may have a long history suggestive of benign biliary tract disease. The treatment of these lesions is disappointing; the survival rate is extremely low. The only hope for decreasing deaths from carcinoma of the gallbladder is by cholecystectomy before carcinoma develops in patients with gallstones.

Extrapleural Pneumothorax in Pulmonary Tuberculosis.—Of 129 extrapleural pneumothorax operations in 121 patients (eight bilateral operations), 91 were successful and 22 were unsuccessful. There were 17 (13.2%) operative deaths. Most of the poor results and deaths occurred before antibiotics and certain technical improvements were evolved. Moreover, some patients were in such poor condition that no therapy could succeed. Exclusion of such patients might reduce the mortality to less than 4% and operative failures to less than 5%. Extrapleural pneumothorax is indicated in patients with advanced bilateral fibroulcerative tuberculosis who fail to respond to bedrest or sanatorium care and in whom pneumothorax, pneumoperitoneum, or phrenic nerve interruption cannot be instituted or have failed. It is indicated also in those in whom thoracoplasty is too hazardous but who are still in fair general health. In elderly patients with positive sputum, extrapleural pneumothorax is often the only means of rendering the sputum negative. Patients with active disease and positive sputum who have hilar cavities, uncontrolled pulmonary hemorrhage, or who are pregnant, may recover when treated with extrapleural pneumothorax. Young women, in whom thoracoplasty involves psychic trauma, can frequently be helped with extrapleural pneumothorax. This operation lost favor largely because of postoperative complications and poor late results, but close attention to detail and modern drug therapy insure its success. It should not be undertaken lightly, however, as the postoperative management is more difficult than in thoracoplasty. Important innovations in extrapleural pneumothorax technique are that the mesial aspect of the lung should not be stripped from the mediastinum, but stripping from the remainder of the chest wall should be extensive; a small paravertebral incision should be followed by airtight closure, and plombage should not be done immediately, but, later, filling the extrapleural space with mineral oil may be desirable. Streptokinase and streptodornase are helpful in the management of postoperative extrapleural fluid coagulum.

Streptokinase-Streptodornase in Postpneumonic Empyema.—Tillett and associates used streptococcic concentrates containing streptokinase and streptodornase (also referred to as SK-SD) in the treatment of 25 cases of empyema following acute pneumonia. In 14 of the cases, the pretreatment cultures were sterile, and in seven they were positive, yielding pneumococci, Streptococcus viridans, anaerobic streptococci, mixed floras, and Escherichia coli. Twenty-one patients were treated medically with systemic antibiotic therapy, intrapleural injections of solutions of streptokinase and streptodornase and aspiration of exudate with and without intrapleural administration of antimicrobial agents. Four patients were treated with closed thoracotomy combined with enzymatic instillations. Enzymatic therapy was employed in the presence of thick loculated exudates not amenable to satisfactory removal by aspiration, the persistence of bacteriologically demonstrable infection, or a combination of both factors. The contents of sterilized, lyophilized ampules containing mixtures of streptokinase and streptodornase in powdered form were put in sterile physiological saline and promptly injected, since deterioration of the enzymes occurs rapidly after the solution has been made. One cubic centimeter of solution contained approximately 10,000 and 40,000 units of the two substances, respectively, and as much as could be retained was injected. In 18 of 21 patients, including three with the putrid type of empyema, the liquefying action of the enzymes was followed by rapid termination of the disease by crisis or by immediate improvement followed by subsequent progressive defervescence. Lytic enzymatic therapy made possible within 24 hours the extensive evacuation of the loculated encapsulated empyemal cavities, and this was followed by increasing reexpansion of the underlying lung. When infection was demonstrable, the enzymatic débridement was followed by rapid sterilization.

Anomalous Lobe of Lung Arising from Esophagus.—An anomalous lobe of lung communicating with the esophagus by means of a bronchuslike tract was found in the chest of an infant and was successfully removed by operation. The pathological diagnosis in this case was ectopic bronchus and lung originating from the esophagus, and chronic pneumonia. The embryologic origin of the esophagus and respiratory system from the gut is briefly reviewed. The primordia of the different parts of the respiratory system and esophagus develop within a mass of mesenchyme, which later becomes the mediastinum. It is not difficult to explain most of the congenital anomalies that take place in this region on the basis of the embryologic background.

Banthine® in Ulcer Management.—The bromide salt of beta-diethylaminoethyl-xanthene-9-carboxylate-methobromide (banthine® bromide) was given to 162 patients, 112 men and 50 women, whose average age was 43 years and who had uncomplicated duodenal ulcers. A schedule of 50 mg. of the drug at six-hour intervals was adopted during the day, 150 to 200 mg. at bedtime, and 100 mg. six hours thereafter. This regimen with minor individual adjustments was achieved in 82% of the patients and was deemed adequate for symptomatic relief, gastric secretory inhibition, and suppression of gastric hypertonicity. When radiologic evidence of ulcer healing appeared it was considered permissible to begin a dose of approximately one-half the therapeutically effective dose. This maintenance dose is considered necessary to prevent recurrence, since no etiologic factor is eradicated. With this schedule 136 patients were completely relieved from pain within an average of 38 hours; 12 had less intense and less frequent discomfort; 11 claimed no pain relief, and three patients had complications. Nocturnal waking pain, present in 116 patients, was relieved in all but seven instances. Nausea and vomiting, which occurred in 86 patients, was relieved in all but one. Pyrosis, present in 32 patients, was not improved, and 54 additional complaints of pyrosis were precipitated by the drug. Other side effects were objectionable salivary suppression, occurring in 78 patients, significant mydriasis in eight patients, dysuria in 13 patients, constipation without dyschezia in 102 and with dyschezia in 36, and mild vertigo and weakness in six. A curarelike reaction was observed in one instance. Roentgenologic evaluation at three month intervals suggested a beneficial effect but was not conclusive. In view of the fact that the authors' patients had no supplemental diet or medication, the response to banthine® bromide was impressive. The drug is to be considered an effective adjunct to but not a substitute for basic ulcer management. A longer follow-up is necessary for complete evaluation, because recurrences may occur at any time. It is probable that one can now control hypertonicity as a factor in ulcer occurrences and recurrence.

Infants Born of Tuberculous Mothers.—Fifty-five infants born of tuberculous mothers between 1943 and 1945 are reported on. Twenty-four (44%) infants were premature, and 31 (56%) were full term infants. The incidence of prematurity is exceedingly high in the offspring of tuberculous mothers, ranging from 23 to 64%, depending on the severity of the disease in the mother. The prematurity is related to the severity of the disease in the mother not because of the tuberculous infection but because of the poor nutritional status of the mother. The infants were immediately removed from contact with the mothers. Four infants died within the first 24 hours. Necropsy was performed, but none showed evidence of tuberculosis. Despite the handicap of prematurity that characterized 20 of the remaining 51 children, all survived. A standard diet of evaporated milk, dextri-maltose® with the supplementation of ascorbic acid, percomorph oil, and calcium caseinate given the premature as well as the full term infants resulted in a growth pattern and development comparable to that observed in premature and full term infants born of healthy mothers. About one-third of the infants were followed up for about two years. Results of Mantoux tests were negative, as were results of roentgenologic examination, when the infants had reached the age of 2. In infants separated from their tuberculous mothers at birth who continue to remain in an environment free of tuberculosis the disease does not develop. Although congenital tuberculosis does undoubtedly occur, the author did not observe a single case of transplacental tuberculosis in a series of 260 infants born of tuberculous mothers, even though 17.6% of the mothers died of advanced tuberculosis shortly after delivery.

Ligation and Heparin in Thromboembolic Disease.—During the five year period terminating Dec. 31, 1949, several methods were used to reduce the incidence of thromboembolic complications in 27,802 surgical patients. Routine measures of prophylaxis included frequent change of position in bed, early ambulation, compression bandages applied before anesthesia and operation and maintained until discharge, deep breathing exercises, prompt replacement of blood loss, avoidance of abdominal distention and of heavy sedation, and prevention of dehydration, electrolyte imbalance, and hypotension. In patients in whom there was an unusual risk of a thromboembolic complication, especially when there was a history of previous embolism, anticoagulants and prophylactic superficial femoral vein ligation were employed. Therapeutic procedures included the following measures: for phlebothrombosis, bilateral superficial femoral vein ligation or anticoagulants; for acute thrombophlebitis, lumbar sympathetic block or anticoagulants; for extension of thrombus proximal to femoral vein, anticoagulants; for suppurative iliofemoral or pelvic thrombophlebitis, ligation of the iliac veins or vena cava; for pulmonary infarction without dyspnea, bilateral superficial femoral vein ligation or anticoagulants; for massive pulmonary embolism, heparin, 50 mg. given intravenously at once. Atropine, papaverine, oxygen, and morphine were also given. Despite efforts to reduce their incidence, thromboembolic complications occurred in approximately 1% of patients after operation. Phlebothrombosis and thrombophlebitis occurred in 0.65%, nonfatal pulmonary infarction in 0.205%, and fatal pulmonary embolism in 0.11% of the patients. The incidence of fatal pulmonary embolism probably can be reduced only by effective mass prophylaxis, by a clearer understanding of the factors causing venous thrombosis, or by the development of tests that indicate incipient thrombosis so that effective therapy can be instituted.

Raynaud's Disease.—Blain and associates propose the adoption of the terms "Raynaud's disease" and "Raynaud's syndrome" as substitutes for the terms "primary Raynaud's phenomenon" and "secondary Raynaud's phenomenon" in the belief that this will simplify the classification of the disorders under discussion. Raynaud's disease is the primary and idiopathic form of the phenomenon of paroxysmal spasm of the digital arteries, producing acral ischemia and cyanosis of the digits, bilaterally and symmetrically, in response to cold and emotions; it is usually relieved by warmth. In its severe form there is a recurring, painful spasm, narrowing the local vessels, deforming the digits (usually the fingers), and leading to local ulceration and necrosis. The disease is frequently seen in young women who show other evidence of vasomotor instability. Raynaud's syndrome is always the result of some underlying vascular or other disease. Commonest of the underlying diseases are the obliterative vascular diseases (arteriosclerosis obliterans and thromboangiitis obliterans), the collagen diseases (scleroderma, rheumatoid arthritis, dermatomyositis), thermal injury (frostbite and burns), mechanical trauma (use of vibrating tools, such as the pneumatic hammer), and the Naffziger syndrome (cervical rib and scalenus anticus syndrome). Raynaud's syndrome may also result from lesions of the central nervous system. The prognosis of true Raynaud's disease was studied in 100 patients, who had been followed for at least five years. One-fourth progressed to a point of tissue loss (ulceration, necrosis, and superficial gangrene) or to a point at which pain and other symptoms caused sufficient disability for the patients to submit to sympathectomy. In most of the remaining three-fourths of the cases the disease ran a benign chronic course for from five to 55 years. The one-fourth classified as severely progressive cases were characterized oftenest by an onset of symptoms between the ages of 15 and 30 years and rapid progression. Cases in which attacks can be precipitated only by cold or in which functional factors are not particularly prominent, especially if the onset of the disease is before the age of 15 or after the age of 35, are not likely to progress to tissue loss or the need for operation. The majority of patients undergoing dorsal sympathectomy by techniques used in the past will obtain at least temporary relief of symptoms. It is believed that more patients will obtain permanent relief following the radical postganglionic sympathectomies now performed. Clinical observations uphold the theory that Raynaud's disease is due to both a local fault in the digital vessels and superimposed abnormal vasomotor tone.

Surgical Management of Secondary Hypersplenism.—Idiopathic thrombopenic purpura and congenital hemolytic icterus are two of the most notable examples of primary hypersplenism. Splenectomy is usually beneficial in both conditions. In secondary hypersplenism, first the spleen is enlarged; second the bone marrow must be normally active or hyperactive; third there is evidence in the peripheral blood of a reduction below normal of one or more or all of the cellular elements, and fourth there must be some primary disease entity, with involvement of the spleen either directly or indirectly. Splenectomy in properly selected cases is frequently followed by worthwhile improvement in the peripheral blood, although the course of the primary, basic disease may not be influenced significantly. Blakemore, Whipple, and Rousselot have developed satisfactory shunting procedures for the relief of portal hypertension on both an intrahepatic and an extrahepatic basis. In patients with secondary hypersplenism due to a congestive splenomegaly (portal hypertension), great benefit may be derived by combined splenectomy and splenorenal shunt. Five illustrative cases are presented.

Mass Chest Surveys for Tuberculosis.—Lönnerblad feels that case finding by means of chest photofluorography of the entire population is not likely to reduce the incidence of tuberculosis greatly. As causes for this failure he mentions the relatively poor results of present therapeutic measures, even in the early stages of pulmonary tuberculosis and the fact that it is not economically feasible to isolate effectively all persons with arrested or intermittently open tuberculosis of the lungs. Moreover, in persons infected with pulmonary tuberculosis between x-ray surveys a rapidly progressive process may unexpectedly develop and so there is time for a significant number of persons to be infected before the diagnosis is established. The author concludes that without more effective economic aid to persons with tuberculosis and to susceptible groups of the population and without widespread BCG inoculation, photofluorographic examinations can hardly produce the desired results.

Tolerance Dose in Radiologic Work.—Hematological examinations and measurements of the exposure to ionizing irradiations of the personnel in the radium and roentgen departments of the hospital in Aarhus, Denmark, disclosed that the tolerance dose, which so far was supposed to be 100 milliroentgens per day, is fairly close to the limit of tolerance of the hematopoietic system. Since there is a risk of other harmful effects of exposure to this amount of radiation, it is suggested that 100 milliroentgens should be regarded as the maximum permissible exposure per week rather than per day.

Pyloric Stenosis in Four First Cousins.—There is evidence that genetic factors play some part in the causation of pyloric stenosis. Identical twins appear to be more often both affected than fraternal twins of like sex, and the incidence in brothers and sisters of children with pyloric stenosis is higher than in the general population. A family of 11 brothers and sisters is described, five of whom have had children. Of these, four have had a child with pyloric stenosis in which the diagnosis was confirmed at operation. This family provides additional evidence that genetic factors are in part responsible for the condition.

*Cancer of the Stomach in Uruguay. P. Larghero Ybarz, I. Carrera, H. Cardeza and R. Minatta.—p. 275.

Cancer of the Stomach.—Gastric cancer is responsible for 25% of all deaths from cancer in Uruguay. The authors report on 125 cases of gastric cancer. Sixty-five were treated by resection; the remainder were inoperable. The procedure of choice was an enlarged regional gastrectomy, either total or subtotal, including resection of all the regional chains of lymph nodes. The type of gastrectomy and the route of approach depended on the site and extension of the cancer. The authors favored subtotal gastrectomy. The abdominal route was preferred for total gastrectomy, while the transthoracic route was chosen for resection of the cardia and the fundus of the stomach. Splenectomy was often indicated. Total gastrectomy was performed on 12 patients and subtotal gastrectomy on 53. Of the 12 patients who had total gastrectomy six died within the first week (50% operative mortality). Four died between three months and one year after the operation. Two patients are living, four and 32 months, respectively, after the operation. Transthoracic gastrectomy was performed in six patients (two total and four subtotal gastrectomies). Three patients died (50% operative mortality), one from peritoneal cancer a few months after the operation, and two patients are living, two and three years after the operation, respectively. In the 49 cases in which subtotal gastrectomy was done by the abdominal route the postoperative mortality was 21.4%. Although nearly all the patients in these groups were first seen in an advanced period of cancer, 50% of them were living between one and four years after the operation; only six in the whole group are living five years after the operation.

*Consideration of Certain Sources of Error in Diagnosis of Gastric Ulcer. E. D. Palmer.—p. 161.

Errors in Diagnosis of Gastric Ulcer.—Observations on 30 patients in whom errors were made in the positive or negative diagnosis of gastric ulcer demonstrated the complementary functions of roentgenography and gastroscopy in the diagnosis of gastric disease. In only one of the misdiagnosed cases did the roentgenographic and gastroscopic diagnoses agree in the error. The diagnostic errors were correlated with the failure of the two methods to corroborate each other. The greatest number of errors occurred in lesions on the lesser curvature of the antrum. This region of the stomach presents most difficulties to both x-ray and gastroscopic interpretation. To the radiologist it is often an area of confusing dynamic deformities and to the gastroscopist it often constitutes an entirely blind area. In cases of lack of conformity between gastroscopic and roentgenologic diagnosis, careful evaluation is necessary before radical treatment is instituted. As a rule, the more serious diagnosis should be considered as the correct one.

Allergy to Aspirin.—The drug most commonly causing severe allergic reactions is acetylsalicylic acid (aspirin). The most frequent symptom is asthma, but urticaria, angioneurotic edema and rhinitis are fairly common. The occurrence of definite sensitivity to acetylsalicylic acid was observed in 22 of 830 patients with asthma. All 22 patients manifested asthma when given small amounts of acetylsalicylic acid. Several also had urticaria, angioneurotic edema, and rhinitis. In addition, three were allergic to antihistamines. All the patients were adults, seven men and 15 women, between the ages of 27 and 64. Half of them had a severe degree of asthma as compared to only 13% of the entire group of 830. Five of the 22 patients died in the four year study period. Necropsy was performed in three, who showed the characteristic changes of fatal bronchial asthma. Clinical reactions to acetylsalicylic acid are usually violent and rapid.

Cortisone and ACTH in Rheumatic Fever.—Twenty-three children between the ages of 3 and 14 with rheumatic fever were treated with either cortisone or pituitary adrenocorticotropic hormone (ACTH). Cortisone was administered twice daily. The total daily dose was 100 to 200 mg. in 24 hours. Pituitary adrenocorticotropic hormone was given every four hours in a total daily dose of 40 to 80 mg., depending on body weight. Most children were treated for four to six weeks. When evidence of a relapse occurred, treatment was resumed and continued for two to three additional weeks. Fever and arthritis were promptly relieved. The sedimentation rate was restored to normal in most patients in three weeks. There was an increase of body weight by an average of 1½ lb. (0.73 kg.) a week during treatment. Gallop rhythm frequently disappeared. Subcutaneous nodules disappeared in approximately three weeks in three patients. Choreiform movements ceased in three weeks in four cases. There was usually an appreciable rise in hemoglobin and hematocrit during treatment. There was no significant change in heart murmurs. Changes in heart size were not significantly different from those observed in children treated with bed rest and salicylates. The sedimentation rate frequently rose after administration of the hormone was discontinued, but usually the rise was transient. In other cases administration of the drug had to be resumed for an additional period. Patients with chronic heart failure were not improved by such treatment, and in one patient the failure became more pronounced during treatment. Two patients with acute heart failure in the first attack of rheumatic fever were quickly and dramatically improved when hormone therapy was instituted.

Surgical Treatment of Coronary Artery Insufficiency.—When the internal mammary artery of a dog is experimentally implanted into the ventricular myocardium it forms new arterial branches that anastomose with the left coronary circulation. When this occurs the heart is protected against infarction following the ligation of the anterior descending branch of the left coronary artery. Those animals that survive such a ligation, however, die or an infarction develops when the implanted internal mammary artery is occluded. Thus an internal mammary coronary artery anastomosis has functional value in relieving artificially produced coronary artery insufficiency. These experiments suggest that an internal mammary artery implant may be valuable in the treatment of human coronary artery insufficiency. The internal mammary artery was implanted in the ventricular myocardium of three patients with coronary artery insufficiency, who were carefully selected and treated by a medical-surgical team. The use of quinidine preoperatively and postoperatively and of procaine hydrochloride during the operation is important in preventing ventricular fibrillation. The first patient died two and a half days after operation. Death was due to a recent coronary thrombosis, which, according to the authors, developed because of the low blood pressure that was present throughout the operation. Necropsy revealed that the internal mammary artery was completely patent 62 hours after the implantation. Despite the burying of an open vessel in the myocardium, there was no evidence of hemorrhage or intramural hematoma. In the two other patients the blood pressures were maintained above 100 mm. of mercury throughout the operation by means of a continuous intravenous drip of phenylephrine (neo-synephrine®) hydrochloride. Both patients recovered and appeared to have been improved at the time of discharge. It is still too early for definite evaluation of the operative results.

Aureomycin in Psittacosis.—Eight cases of psittacosis, six of them occurring in two families, are reported. The patients were between the ages of 21 and 48. The infection was transmitted by parrots bred in Germany. The course of the disease was moderately severe or severe in seven patients and mild in the youngest patient. One patient died. All patients had the characteristic symptoms of the disease. Necropsy was performed in the fatal case, and the psittacosis virus was isolated. The complement fixation reaction was strongly positive in four patients and doubtful in three. Treatment with quinine and calcium combined, sulfathiazole, penicillin and streptomycin failed. Three patients were treated with aureomycin. A dose of 500 mg. every four hours was given orally. The total dose administered was 4,000 mg. The temperature was restored to normal within 24 hours, and all patients recovered. The effect of the drug did not depend on the time at which treatment was instituted. The prognosis of psittacosis has been decisively improved by the possibility of treatment with aureomycin.

•Relations Between Ulcer Disease and Adrenals: Hormone of Adrenal Cortex, Adrenalin, Sodium Chloride and Histamine in Therapy of Peptic Ulcer. L. Biró and G. Nagy.—p. 169.

Peptic Ulcer and the Adrenals.—The following evidence suggests a relationship between peptic ulcer and the adrenals: 1. Normal functioning of the adrenal cortex is necessary for maintaining the mucous membranes of the gastrointestinal tract in a healthy condition. 2. Twenty per cent of patients dying from Addison's disease have peptic ulcer. 3. Hypotension, one of the most important symptoms of adrenal insufficiency, is also frequent in patients with peptic ulcer. These and other indications induced a number of investigators to treat ulcer patients with desoxycorticosterone acetate. This substance was employed in the 133 ulcer patients reviewed here. Many of these patients had symptoms characteristic of adrenal insufficiency; for instance, 42.1% had asthenia, 50% had low blood pressure and about 60% had a positive reaction to the (Cutler) potassium and water tolerance test. The 17-ketosteroids were determined in 14 ulcer patients, and in 10 the values were abnormal. It was found that treatment with desoxycorticosterone acetate caused rapid disappearance of the peptic ulcer, particularly in patients who had signs of adrenal insufficiency. Treatment with sodium chloride and epinephrine produced similar therapeutic results. There was a parallelism between the healing of the ulcer and the disappearance of the signs of adrenal hypofunction. Extracts of the adrenal cortex are far less efficacious. Histamine treatment is successful mainly in gastric ulcer.

•Cervical Vertebral Syndrome. P. Nava.—p. 195.
•Interesting Clinical Syndrome: Melanodermia, Cirrhosis of the Liver and Diabetes Mellitus. W. Saad Hossne and J. E. Dutra de Oliveira. —p. 275.

Cervical Vertebral Syndrome.—Nava reports on two patients with a malformation of cervical vertebrae that results in contact of two or more spinous processes on extension of the neck (kissing spine). This was associated with local and radiating pain. A similar condition has been described in the lumbar region by Michotte. One of the patients, a woman aged 46, had severe pain in the neck, contraction of the superior and medium bundles of the trapezius, forward projection of the head and limited rotation and flexion of the neck, extension of which was impossible because of stabbing pain. Roentgen examination showed contact of the spinous processes of the fourth, fifth and sixth cervical vertebrae. The other patient, a man aged 54, complained also of pain in the neck radiating to the right shoulder joint and shooting pain in the right arm and hand. Roentgen examination showed contact of the spinous processes of the fourth and fifth cervical vertebrae. These two cases confirm Michotte's observations and establish the existence of a new syndrome of pain in the neck and shoulders, for which the author suggests the name of cervical vertebral syndrome or Michotte's syndrome.

Interesting Clinical Syndrome: Melanoderma, Cirrhosis of the Liver and Diabetes Mellitus.—The case described by the authors is rare. The patient, a girl 14 years old, had from the age of 8 a progressive disease characterized by pigmentation of the skin, hepatic cirrhosis with splenomegalia and diabetes mellitus simulating hematochromatosis. Neither biopsy of the skin nor postmortem examination revealed existence of hemosiderin. The authors concluded that the case was one of cirrhosis of the liver in association with diabetes mellitus and melanoderma of unknown origin. The suprarenal cortex was found to be normal by necropsy.

Methods for Rh Group Determinations.—According to Poole and Williams, the most reliable method for Rh group determination is probably the standard tube method. This technique has only one serious disadvantage: it may take as long as two hours to perform, although occasional high avidity anti-D serums will give clearcut results in 30 minutes or less. For emergency Rh typing quicker procedures are desirable. This report compares three methods. In 917 determinations of Rh groups by the Chown capillary tube method, 20 erroneous results were obtained, nine being false positive and 11 false negative. At the same time, observations were made with the standard tube method, which gave no false results in this series. False positive Chown tests appear to be due to rouleau formation when suspensions of cells in serum are used; this can be avoided by the use of saline suspensions. False negative results can be obtained by the Chown test if insufficient time is allowed for the development of a positive result. Factors delaying its appearance are dilution, the use of saline as opposed to serum suspensions and the use of blood specimens more than five days old. A rapid method, which gave no discrepancies in 450 tests carried out concurrently with the standard tube method, consisted of the incubation of the tube for 10 minutes at 37 C. followed by centrifugation for five minutes at 2,000 to 2,500 rpm.

Premature Separation of Placenta: Fetal Suicide.—A primigravida, 17, was hospitalized with mild toxemia of pregnancy. With bed rest and sedatives, the blood pressure fell in a few days and the edema disappeared. Discharge from the hospital seemed justified when suddenly, following particularly violent fetal movements, she complained of severe abdominal pain and vaginal bleeding. She was in moderate shock, and the uterus was stony hard and tender. No fetal heartbeat could be heard. After a rapid labor she was delivered of a well-preserved, stillborn fetus, followed immediately by the placenta and a mass of retroplacental clot. The umbilical cord was wrapped once around the right ankle of the child, then twice round the right wrist and once around the right hand. The length of the cord was 23 in. (60.96 cm.) but, because of the turns around the limbs, only 4 in. (10.16 cm.) of cord remained free between the right hand and the placental insertion, which was eccentric. The separation of the placenta was probably due to avulsion of the placenta as a result of traction on the cord by the fetus itself. It seems probable that the mechanism that Duff (1950) described as a possible cause of antenatal separation of the cord has been operative in this case. The mild toxemia may have been associated with some decidual deterioration, which may have made the placenta more liable to separation as a result of traction by the fetus.

Abnormal Lactation.—Five cases of abnormal lactation are reported, one in a young virgin and the rest in women who had borne children. In one case lactation followed hysterectomy, in two there was evidence of pituitary overactivity, and in one there was pituitary deficiency. It is known that nursing may prolong lactation almost indefinitely in women who have previously breast-fed children. Nursing in combination with strong psychogenic stimuli or even psychotic symptoms may initiate lactation in nulliparas or virgins. Possibly, organic brain disease affecting the mesencephalon or hypothalamic nuclei may occasionally be responsible. In another group, endocrine influences, due to pituitary tumors with excessive output of anterior lobe hormones, or adrenal cortical tumors, may stimulate lactation. The only point of possible significance in the 16 year old girl whose case is reported is that the output of 17-ketosteroids had increased. If this is confirmed during further observation it is possible that lactation may be due to pituitary hyperfunction or some hypercorticoid syndrome. The almost complete amenorrhea suggests combinations of endocrine imbalance leading to persistent lactation and uterotubal atrophy.

*Corneal Dystrophy and Cataract as Sequel of Thyroidectomy. H. Pau.—p. 75.

Ocular Complications in Leptospiroses.—The following benign leptospiroses are briefly discussed: (1) harvest, field or mud fever, in which Leptospira grippotyphosa, L. sejroe and L. australis have been isolated; (2) canicola fever (L. canicola) and (3) swineherd's disease (L. pomona). The histories of eight patients are presented in whom ocular symptoms developed, during infection with L. canicola in three cases, L. pomona in four cases and L. australis in one case. Six of the patients had iridocyclitis and two had temporary papilledema. It is assumed that the papilledema was directly connected with the meningitic process that characterized the leptospirosis. The iridocyclitis that develops in the course of leptospirosis may be either a benign form, which heals without sequelae and causes only slight opacities in the vitreous humor, or a more serious form, which is resistant to treatment, causes a great decrease in visual acuity and generally causes a characteristic membranelike opacity in the vitreous. One of the eight patients here reviewed had four successive attacks of iridocyclitis in the course of 18 months. As far as the authors were able to ascertain, this was the first case of this type that occurred in connection with leptospirosis. They also concluded that the severe forms of leptospiroses were the ones most likely to produce ocular symptoms. On the other hand, there was apparently no connection between the occurrence of ocular symptoms and the type of Leptospira.

Corneal Dystrophy and Cataract After Thyroidectomy.—Severe tetany developed in a woman aged 55, who had been subjected to thyroidectomy on account of toxic goiter. Her blood calcium content decreased to 8 mg. per cent, and she had tetanic attacks. Tetanic cataracts became evident six months after operation, and somewhat later parenchymatous opacities of the cornea developed in both eyes with the characteristics of an epithelial corneal dystrophy. Whereas the lenticular opacities were probably the result of lesions of the parathyroids, the inflammation of the cornea was presumably caused by lesions of the thyroid, parathyroids, and cervical sympathetics and by sympathetic changes incident to the menopause.

Adrenals in Collagen Disease.—Simultaneous treatment with lyophilized anterior pituitary and cortisone produces the picture of "collagen disease" or "hyalinosis" in the rat, characterized by eventually fatal malignant nephrosclerosis with myocarditis (resembling that seen in acute rheumatic fever) and periarteritis nodosa. Adrenalectomy completely prevents these renal and cardiovascular lesions. It is concluded that the active factor in lyophilized anterior pituitary exerts its principal toxic effects only in the presence of functioning adrenal tissue. The so-called growth hormone, or somatotropic hormone, accurately reproduces the hyalinosis syndrome caused by lyophilized anterior pituitary. This effect of somatrotropic hormone can be inhibited by cortisone but only under conditions that permit the latter to induce pronounced adrenocortical atrophy. Cortisone fails to cause adrenal involution in rats treated with lyophilized anterior pituitary, since the latter is rich in pituitary adrenocorticotropic hormone. This agrees with the view that lyophilized anterior pituitary preparation causes hyalinosis by virtue of the somatotropic hormone it contains and that the pathogenicity of somatotropic hormone depends largely on the functional capacity of the adrenal cortex. In many respects pituitary adrenocorticotropic hormone and the glucocorticoids (such as cortisone), on the one hand, and somatotropic hormone and the mineralocorticoids (such as desoxycorticosterone), on the other, have diametrically opposed effects. Hence, the requirements for pituitary adrenocorticotropic hormone or cortisone in clinical medicine are probably also largely dependent on the presence of somatotropic hormone and of mineralocorticoids in the organism.

Female Carrier of Hemophilia.—A clinical and laboratory study of the female carrier of hemophilia was made in an attempt to confirm the claims that a demonstrable coagulation defect exists in these women. The carriers, as a group, were more liable to abnormal hemorrhage, especially after tooth extraction. Occasional abnormal results were also obtained with laboratory tests for coagulation time and prothrombin consumption during coagulation. These results were too indefinite and inconsistent to be of diagnostic value. The methods at present available for measuring the efficiency of blood coagulation do not seem to be sensitive enough to unmask the relatively slight defect that may be present in the female carrier of hemophilia. In no case in the female carrier group did the clinical history and laboratory observations bear more than a superficial resemblance to hemophilia in the male. In view of the abnormalities found in some of these carriers it is hoped that future work may reveal some constant characteristic that will allow their recognition in early life.

Etiology of Diabetes Mellitus.—The etiology of diabetes mellitus presents a number of complicated problems. The isolation of insulin, apart from its incalculable value in clinical medicine, stimulated a large amount of clinical and experimental work, which is now turning opinion away from Allen's concept of the primarily pancreatic origin of diabetes and even from the idea that it is a single disease entity. Autopsy material from patients who have died from diabetes has failed to show characteristic changes in the islet cells in many instances. Diabetes seldom occurs either during the course of or as a sequel to acute pancreatitis. Assays of the insulin content of the pancreas from diabetics have on occasion yielded normal values. Downie concludes that the experience of the past 30 years has swung medical thought and opinion away from the view that diabetes arises as a result of a primary pancreatic deficiency. The one essential feature of diabetes mellitus is hyperglycemia, which may arise, at least in some instances, from increased utilization, destruction, or inhibition of insulin rather than from a primary decrease in its production. Much remains to be discovered, but at present diabetes mellitus is better regarded as a symptom complex resulting from any of several causes than as a disease sui generis.

Aureomycin in Urinary Infections.—Aureomycin has a wide therapeutic spectrum in that it is active against a large number of gram-positive as well as gram-negative organisms. Its importance in urologic therapy is due to the fact that it is active against gram-negative organisms of the coliaerogenes group. During prolonged treatment with aureomycin these organisms do not show a tendency to become resistant as is the case during treatment with penicillin and streptomycin. Aureomycin is almost nontoxic; daily oral doses of from 25 to 50 mg. and even up to 300 mg. per kilogram of body weight are tolerated. It has no harmful effects on liver function, hematopoiesis, metabolism, or nervous functions. Nausea, vomiting, and a sensation of pressure in the upper abdomen are occasionally observed. The histories are presented of several patients who had urinary infection and who were treated with aureomycin. Most of these patients could be discharged with sterile urine; their fever rapidly subsided, and duration of treatment and of hospitalization was shortened. Control examinations in two patients one month later revealed that the urine was still sterile.

*Mercury Poisoning as Cause of Acrodynia. H. J. Peters.—p. 378.

Cause of Hemorrhages During Use of Aminopterin.—Since van Creveld and his associates were unable to explain the hemorrhages occurring in patients receiving 4-aminopteroylglutamic acid (aminopterin) for leukemia or other diseases on the basis of changes in the blood platelets or heparinlike substances, they investigated other factors that play a part in coagulation, particularly the Ac-globulin (accelerator globulin). Their studies in two patients indicated that a decrease in this clotting factor is probably responsible for the hemorrhages that frequently occur during treatment of leukemia with aminopterin.

Mercury Poisoning as Cause of Acrodynia.—In the 2 year old boy whose case is reported acrodynia developed as the result of treatment with mild mercurous chloride (calomel). Patch tests proved hypersensitivity to mercury, and the urine contained large amounts of mercury. The symptoms of acrodynia subsided following treatment with dimercaprol (BAL). The author cites several other reports from the literature in which children in whom acrodynia developed following treatment with mercury preparations were effectively treated with dimercaprol.

Genital Tuberculosis in Women.—Tuberculosis of the female genitalia usually develops by the hematogenic route from foci in other organs; the uterine tubes are nearly always involved, whereas the ovaries are involved in only about a third of the cases and the uterus (endometrium) in from one-half to three-fourths of the cases. Clinically, tuberculous salpingitis does not differ from other forms of adnexitis. Of the various methods used to establish the definite nature of the adnexitis, curettage is the one most widely used, although exploratory laparotomy, salpingography, and culdoscopy are also occasionally employed. Curettage is occasionally followed by exacerbation of the tuberculous process, and a case is cited to illustrate this. Inoculation of menstrual blood into guinea pigs is a harmless method, which can be valuable in establishing the tuberculous nature of salpingitis, as is demonstrated by a case report. Paraaminosalicylic acid seemed to be of no particular value in tuberculous salpingitis.

Pulmonary Changes in Brucellosis.—A man, 24, had pulmonary symptoms and roentgenologic signs of pulmonary involvement. He had had contact with cattle infected with brucellosis, and his pulmonary symptoms could be traced to no other cause than the brucellosis. This case induced the authors to investigate the occurrence of pulmonary changes in nine other cases of brucellois in their records. In six of these cases cough was an im-

logic examination. Patients with indolent ulcers were excluded. After the production of a moderate pneumothorax, roentgen examination was done so that it might be ascertained whether the layers of the pleura were free. With the patient under local anesthesia and with the aid of a trocar, the thoracoscope then was pushed into the pleural cavity, within the anterior to median axillary line through the fifth to the sixth intercostal space. The entire course of the sympathetic nerve and the branching off of both the splanchnic nerves could be seen in the posterior thoracic cavity. A simple device, consisting of a bicycle spoke whose end had been bent at an angle of 130 degrees and ground to a point, was inserted with the aid of a second trocar puncture. A slight incision was made easily in the pleura, and the splanchnic nerve was wound around the point of the spoke. The patient felt a characteristic pain in the gastric region on either the left or the right side, and microscopic examination of the removed nerve provided additional proof that the proper nerve had been removed. After the intervention the patients were followed up for five to 21 months. All the patients had immediate pain relief. Some had vomited seven to eight times a day before the intervention. No vomiting occurred after the intervention. Increases in weight up to 40 pounds (19 kg.) were observed within one year. All patients were placed on a normal diet and remained free of complaints. Ten days to six weeks after the intervention the ulcer niche could no longer be demonstrated on roentgenological examination. The regular presence of two to three myelinated fibers was revealed by systematic examination of the removed splanchnic nerve, and thus again physiological proof was provided of the presence of vagus fibers in the splanchnic nerve. An alternate functional play between the apparently antagonistic systems of vagus and sympathetic nerve is suggested. Overstimulation of the sensitive sympathetic nerve in connection with emotion causes secondary stimulation of the vagus. The splanchnicectomy eliminates pain, and thus the stimulating impulses from the center to the neuromotor-secretory system of the vagus are abolished.

Intravenous Administration of Paraaminosalicylic Acid.—Continuous intravenous drip of paraaminosalicylic acid solution has been used satisfactorily for the treatment of tuberculous meningitis. Intermittent intravenous administration of a solution of sodium paraaminosalicylic acid in distilled water was used in the treatment of 40 tuberculous patients, in 14 of them before and after excision of the lung or decortication, in nine during acute exudative tuberculosis of the pleura, in seven following recent hematogenous or bronchogenous dissemination and in 10 after pneumonolysis or plastic operations. Every day for 10 to 12 days 500 cc. of a 4% solution were administered slowly (30 drops per minute) within 3 to 5½ hours. The advantage of the intravenous over the oral administration of paraaminosalicylic acid consists in the high concentration of the drug in the blood and in its independence of the gastrointestinal tract. The drug was well tolerated. Nausea, vertigo or tendency to collapse were observed only if the solution was administered in less than three hours. The prothrombin time did not diminish, and the incidence of distant thrombosis was not increased. Intravenous administration of paraaminosalicylic acid has proved particularly valuable after extensive surgical procedures on the lungs, because the site of the operation is constantly washed by a pleural exudate containing large amounts of the drug. With a single daily intravenous infusion of the drug an effective concentration was obtained in the pleural exudate of patients with tuberculosis of the pleura, thus making repeated intrathoracic injections of irritating hypertonic solution unnecessary. Massive hematogenous dissemination was controlled with six intravenous infusions of 20 gm. of paraaminosalicylic acid combined with penicillin and sulfamethazine. Patients who hardly responded to the oral administration of the drug responded well to intermittent intravenous administration. This method proved particularly effective in those cases in which a most intensive bacteriostasis had to be obtained over a short period. Intermittent intravenous administration of paraaminosalicylic acid should be combined with streptomycin therapy whenever possible.

*Transmission of Malaria. J. Lebon and G. Senevet.—p. 753.
Treatment of Acute Malaria. J. Lebon and M. Fabregoule.—p. 755.

Transmission of Malaria.—Malaria may be transmitted not only by the bites of infected mosquitoes but also by blood transfusion, contaminated hypodermic syringes, and prenatally. The possibility of the passage of plasmodia from the mother to the fetus is to be considered as established by the demonstration of plasmodia in the blood of the umbilical cord or in the organs of a newborn infant. Further proof of this mode of transmission has been provided by the occurrence of attacks of malaria in newborn infants several days after birth in countries in which malaria is not endemic. Transmission of malaria by blood transfusion may be intentional, as in fever therapy. Involuntary inoculation by blood transfusions, on the contrary, is a regrettable complication, which may be prevented by blood tests performed on the donors before the transfusion, although it must be admitted that often parasites could not be demonstrated even in thick films obtained from donors with malaria. Plasmodium malariae was the pathogenic agent observed most frequently by occidental authors in cases of this type. It seems that the risk of transmission has not been reduced by the use of preserved blood because of the maintained vitality of the plasmodia. More than 200 cases of transmission of malaria by contaminated hypodermic syringes, 47 of them fatal, have been listed in world literature. The authors emphasize the great sensitivity to the malarial parasites, and particularly to P. falciparum, of the persons to whom the disease has been transmitted in this way. The mortality rate is to be considered 20 times higher than in other patients. Recent investigations on "normal" transmission of malaria by bites of infected mosquitoes revealed that P. vivax may be transmitted to man more easily than P. falciparum and the latter more easily than P. malariae. P. vivax within the mosquito does not suffer from low temperatures during the night, and that partly explains the exclusiveness of this parasite in spring and its distribution as far as to the 60th northern parallel. The sporogenic cycle of P. falciparum does not occur at a nocturnal temperature below 16 C., and, therefore, except for the tropics, it is limited to several weeks or months of summer in the temperate zone. P. malariae develops only in a small number of anopheles. The life cycle of P. vivax requires 15 to 18 days, that of P. falciparum 18 to 20 days, and that of P. malariae 31 days. The anopheles, although it may be a carrier of plasmodia, will transmit them to man only if the sporozoites are living and capable of development in man.

Three Cases of Peroneal Muscular Paralysis (Charcot-Marie-Tooth Type) in Siblings. O. Østergaard Jensen.—p. 229.

Clinical Experiences with ACTH in Certain Skin Diseases.—The authors state that their experiences to date allow no definite conclusions as to the field of indication for pituitary adrenocorticotropic hormone (ACTH). The effect of the substance in pemphigus patients calls for further trial; one patient with pemphigus vegetans is symptom-free two months after treatment, and a second patient, with pemphigus vulgaris, had a recurrence a few days after a month's treatment. In psoriasis the results are discouraging, but investigations will be continued, especially with regard to acute erythroderma. Transitory improvement was seen in a patient with exfoliative erythroderma and moderate improvement in one of two patients with scleroderma diffusa. A patient with periarteritis nodosa is unimproved despite prolonged treatment.

portant symptom. There was also another case in which roentgenologic evidence of pulmonary changes was mentioned. "Atypical pneumonia" is fairly frequent in brucellosis, and hemoptysis also is not uncommon in this disease.

Diseases of Respiratory Apparatus in 1951. M. Bariéty and R. Lesobre. —p. 157.
*Objective Results of Treatment with Streptomycin in 1,000 Cases of Pulmonary Tuberculosis in Adults. C. C. Mattei.—p. 163.

Streptomycin in Pulmonary Tuberculosis.—This is a report on 1,000 adults with pulmonary tuberculosis treated with streptomycin during the last four years. Two grams of the drug daily were administered intramuscularly in six divided doses. A total dose of 250 to 400 gm. proved effective in patients with fibrocaseous or caseating lesions and a total dose of 600 to 800 gm. was effective in patients with miliary tuberculosis. Combined penicillin and streptomycin were given to patients with hectic fever and with large open and secondarily infected lesions. Treatment was discontinued 20 days after temperature was restored to normal but was reinstituted 10 days before the institution of pneumothorax or surgical intervention and continued for 10 days thereafter. Preoperative treatment with streptomycin required an average total dose of 60 to 100 gm., and maintenance treatment then required about 250 to 400 gm. Toxic reactions to the drug were not observed, except for a transient morbilliform eruption about the ninth day of treatment and the occasional occurrence of eczema (five cases per thousand). Deafness lasting six months and then disappearing completely occurred in only one patient. Three patients had temporary vertigo. Benign icterus occurred in 80 male patients after the administration of more than 200 gm. of the drug. This untoward reaction was not observed when dihydrostreptomycin was used. Streptomycin resistance of certain strains of Koch's bacillus was observed in vitro, but clinical resistance was negligible. Patients who already had received total doses of 150, 200, 400, and 800 gm. during a first course of treatment with streptomycin with excellent results were benefited to the same extent by a second course of the drug. Rapid defervescence and clearing of the pulmonary fields in patients with acute miliary tuberculosis was spectacular but often only temporary. Rapid clearing of the lungs in these patients was an unfavorable prognostic sign, since 40 of 130 died even though treatment was not discontinued prematurely. In patients with miliary tuberculosis who recovered, clearing of the lungs required at least three months. Highly satisfactory permanent results were obtained in 32 of 60 patients with generalized extensive bronchopneumonia. Streptomycin therapy made it possible to extend the indications for collapse therapy and to improve and accelerate its results. In patients with bilateral pulmonary tuberculosis, streptomycin therapy made possible effective collapse therapy on the less involved side. Combined treatment with penicillin and streptomycin reduced the size of the cavities by one third or more in 40% of 650 patients in whom collapse therapy was not feasible, by one half or more in 25% of these patients, and caused the cavities to disappear completely in 15% of these patients.

*Amicrobic Urethritis of Venereal Origin in Men: Its Treatment with Chloromycetin. J. Tissot.—p. 107.

Amicrobic Urethritis in Men.—While highly satisfactory, permanent results may be obtained with penicillin in gonococcic infections of the urethra in male patients, there has been in France an increased incidence of amicrobic urethritis in men that proved resistant to penicillin and sulfonamide compounds. This type of urethritis was described by Waelsch in 1901, and Harkness recently insisted that this infection is caused by a virus. Seventeen men with amicrobic urethritis, associated with prostatitis in three and with epididymitis in one, were treated with a French brand of chloramphenicol (tifomycine). A dose of 1.50 gm. was given daily by mouth in six divided doses, one tablet of 0.25 gm. every three to four hours. The drug was well tolerated. Treatment was continued for four to six days according to the localization of the condition and its duration before treatment was instituted. All the patients made a complete recovery, but local treatment may occasionally be necessary.

*Treatment of Rheumatic Fever with Rutin and Ascorbic Acid. M. Schnir.—p. 232.

Treatment of Rheumatic Fever.—Schnir administered rutin and ascorbic acid to 15 patients of either sex between the ages of 10 and 60 with rheumatic fever. Four patients were seen during the first month in the first attack of the disease. They had normal hearts. Eleven patients were seen during a recurrence of rheumatic fever. The number of recurrences in these patients varied between one and six. Ten of the patients had a cardiac lesion that was clinically and/or roentgenologically demonstrated. Rutin was given every four hours in five fractional doses varying from 60 to 250 mg. each. Ascorbic acid was given in two fractional doses of 250 or 500 mg. morning and night. The total dose of rutin varied between 5 and 60 gm. The total dose of ascorbic acid varied between 8 and 60 gm. Cure was obtained in all patients, as manifested by control of fever and of cutaneous, visceral, and articular symptoms, reduction of the erythrocyte sedimentation rate, and stabilization or disappearance of clinical, roentgenologic, and electrocardiographic evidence of cardiac disease. Within the first three months after discontinuation of treatment the patients had a recurrence that was controlled by repeated treatment up to a total dose of 500 mg. of rutin and 500 mg. of ascorbic acid. Rutin and ascorbic acid are not followed by toxic reactions or unpleasant late results. The substances potentiate the effect of each other, diminish the permeability of the tissues, and act favorably on the heart disease.

*Intravenous Administration of Paraaminosalicylic Acid (PAS). F. Amberg.—p. 255.

Exeresis of Splanchnic Nerve in Gastroduodenal Ulcer.—Extensive exeresis of the splanchnic nerve down to and below the diaphragm was performed on 29 patients in whom a simple gastric or duodenal ulcer had been demonstrated on roentgenologic examination. Patients with indolent ulcers were excluded. After the production of a moderate pneumothorax, roentgen examination was done so that it might be ascertained whether the layers of the pleura were free. With the patient under local anesthesia and with the aid of a trocar, the thoracoscope then was pushed into the pleural cavity, within the anterior to median axillary line through the fifth to the sixth intercostal space. The entire course of the sympathetic nerve and the branching off of both the splanchnic nerves could be seen in the posterior thoracic cavity. A simple device, consisting of a bicycle spoke whose end had been bent at an angle of 130 degrees and ground to a point, was inserted with the aid of a second trocar puncture. A slight incision was made easily in the pleura, and the splanchnic nerve was wound around the point of the spoke. The patient felt a characteristic pain in the gastric region on either the left or the right side, and microscopic examination of the removed nerve provided additional proof that the proper nerve had been removed. After the intervention the patients were followed up for five to 21 months. All the patients had immediate pain relief. Some had vomited seven to eight times a day before the intervention. No vomiting occurred after the intervention. Increases in weight up to 40 pounds (19 kg.) were observed within one year. All patients were placed on a normal diet and remained free of complaints. Ten days to six weeks after the intervention the ulcer niche could no longer be demonstrated on roentgenological examination. The regular presence of two to three myelinated fibers was revealed by systematic examination of the removed splanchnic nerve, and thus again physiological proof was provided of the presence of vagus fibers in the splanchnic nerve. An alternate functional play between the apparently antagonistic systems of vagus and sympathetic nerve is suggested. Overstimulation of the sensitive sympathetic nerve in connection with emotion causes secondary stimulation of the vagus. The splanchnicectomy eliminates pain, and thus the stimulating impulses from the center to the neuromotor-secretory system of the vagus are abolished.

Intravenous Administration of Paraaminosalicylic Acid.—Continuous intravenous drip of paraaminosalicylic acid solution has been used satisfactorily for the treatment of tuberculous meningitis. Intermittent intravenous administration of a solution of sodium paraaminosalicylic acid in distilled water was used in the treatment of 40 tuberculous patients, in 14 of them before and after excision of the lung or decortication, in nine during acute exudative tuberculosis of the pleura, in seven following recent hematogenous or bronchogenous dissemination and in 10 after pneumonolysis or plastic operations. Every day for 10 to 12 days 500 cc. of a 4% solution were administered slowly (30 drops per minute) within 3 to 5½ hours. The advantage of the intravenous over the oral administration of paraaminosalicylic acid consists in the high concentration of the drug in the blood and in its independence of the gastrointestinal tract. The drug was well tolerated. Nausea, vertigo or tendency to collapse were observed only if the solution was administered in less than three hours. The prothrombin time did not diminish, and the incidence of distant thrombosis was not increased. Intravenous administration of paraaminosalicylic acid has proved particularly valuable after extensive surgical procedures on the lungs, because the site of the operation is constantly washed by a pleural exudate containing large amounts of the drug. With a single daily intravenous infusion of the drug an effective concentration was obtained in the pleural exudate of patients with tuberculosis of the pleura, thus making repeated intrathoracic injections of irritating hypertonic solution unnecessary. Massive hematogenous dissemination was controlled with six intravenous infusions of 20 gm. of paraaminosalicylic acid combined with penicillin and sulfamethazine. Patients who hardly responded to the oral administration of the drug responded well to intermittent intravenous administration. This method proved particularly effective in those cases in which a most intensive bacteriostasis had to be obtained over a short period. Intermittent intravenous administration of paraaminosalicylic acid should be combined with streptomycin therapy whenever possible.

*Transmission of Malaria. J. Lebon and G. Senevet.—p. 753.
Treatment of Acute Malaria. J. Lebon and M. Fabregoule.—p. 755.

Transmission of Malaria.—Malaria may be transmitted not only by the bites of infected mosquitoes but also by blood transfusion, contaminated hypodermic syringes, and prenatally. The possibility of the passage of plasmodia from the mother to the fetus is to be considered as established by the demonstration of plasmodia in the blood of the umbilical cord or in the organs of a newborn infant. Further proof of this mode of transmission has been provided by the occurrence of attacks of malaria in newborn infants several days after birth in countries in which malaria is not endemic. Transmission of malaria by blood transfusion may be intentional, as in fever therapy. Involuntary inoculation by blood transfusions, on the contrary, is a regrettable complication, which may be prevented by blood tests performed on the donors before the transfusion, although it must be admitted that often parasites could not be demonstrated even in thick films obtained from donors with malaria. Plasmodium malariae was the pathogenic agent observed most frequently by occidental authors in cases of this type. It seems that the risk of transmission has not been reduced by the use of preserved blood because of the maintained vitality of the plasmodia. More than 200 cases of transmission of malaria by contaminated hypodermic syringes, 47 of them fatal, have been listed in world literature. The authors emphasize the great sensitivity to the malarial parasites, and particularly to P. falciparum, of the persons to whom the disease has been transmitted in this way. The mortality rate is to be considered 20 times higher than in other patients. Recent investigations on "normal" transmission of malaria by bites of infected mosquitoes revealed that P. vivax may be transmitted to man more easily than P. falciparum and the latter more easily than P. malariae. P. vivax within the mosquito does not suffer from low temperatures during the night, and that partly explains the exclusiveness of this parasite in spring and its distribution as far as to the 60th northern parallel. The sporogenic cycle of P. falciparum does not occur at a nocturnal temperature below 16 C., and, therefore, except for the tropics, it is limited to several weeks or months of summer in the temperate zone. P. malariae develops only in a small number of anopheles. The life cycle of P. vivax requires 15 to 18 days, that of P. falciparum 18 to 20 days, and that of P. malariae 31 days. The anopheles, although it may be a carrier of plasmodia, will transmit them to man only if the sporozoites are living and capable of development in man.

*Clinical Experiences with ACTH Treatment in Certain Skin Diseases. H. Brodthagen, F. Reymann and M. Schwartz.—p. 223.
Plastic Pyeloureteral Operation in Hydronephrosis. P. Fogh-Andersen. —p. 226.
Three Cases of Peroneal Muscular Paralysis (Charcot-Marie-Tooth Type) in Siblings. O. Østergaard Jensen.—p. 229.

Clinical Experiences with ACTH in Certain Skin Diseases.—The authors state that their experiences to date allow no definite conclusions as to the field of indication for pituitary adrenocorticotropic hormone (ACTH). The effect of the substance in pemphigus patients calls for further trial; one patient with pemphigus vegetans is symptom-free two months after treatment, and a second patient, with pemphigus vulgaris, had a recurrence a few days after a month's treatment. In psoriasis the results are discouraging, but investigations will be continued, especially with regard to acute erythroderma. Transitory improvement was seen in a patient with exfoliative erythroderma and moderate improvement in one of two patients with scleroderma diffusa. A patient with periarteritis nodosa is unimproved despite prolonged treatment.

BOOK REVIEWS

General Psychotherapy: Dynamics and Procedures. By D. Ewen Cameron, M.D., D.P.M., F.R.C.P., Professor of Psychiatry, McGill University, Montreal. Cloth. $5. Pp. 304. Grune & Stratton, 381 Fourth Ave., New York 16, 1950.

The author has had extensive experience in treating patients, as well as in teaching students in psychotherapeutic technics. The book is an outstanding example of organization and systematic presentation of a subject that is generally difficult to reduce to a workable classification. The author's viewpoint is not primarily that of the orthodox ego-psychiatrist, but is highly colored by a mechanistic behavioristic point of view with emphasis on conditioning as a most potent factor in determination of human reactions.

The author starts with five basic premises regarding human behavior. These are as follows: (1) that the organism seeks a point of equilibrium between itself and its environment (homeostasis); (2) that the person is incomplete and must therefore seek completion in relation with others; (3) that the organism responds as a whole to any stimulus no matter where applied; (4) that concepts of causality or event sequences must be broadened in order to understand human behavior, and (5) that the problems of behavior are relative to the social and cultural environment of the person.

In speaking of the dynamics of psychotherapy, the author reduces the whole structure of psychotherapy to three pivotal concepts that are based on the preceding premises, and that deal with normalization and adaptability of the nonunitary organism. There is a detailed discussion of the dynamics of psychotherapy and, finally, of the technics of psychotherapy, illustrated with excerpts from tape recordings, which are extensively used by the author. The sections on integrative and directive psychotherapy are well written, logical, and complete. There is an informative chapter on the use of adjuvants of psychotherapy, as well as excellent chapters on group and nursing psychotherapy.

The book is extremely well written and follows a literary style with a logical clear presentation of the material. The printing and format are of good quality. The book should be valuable not only to the general practitioner who is seeking a short introduction to psychotherapy, but also to the teacher of psychiatry who is seeking an organized logical presentation of the subject. There are, naturally, statements by the author that are of a controversial nature, but on the whole the book can be recommended as being one of the best, concise textbooks on psychotherapy.

Psychosurgery in the Treatment of Mental Disorders and Intractable Pain. By Walter Freeman, M.D., Ph.D., F.A.C.P., Professor of Neurology, George Washington University, Washington, D. C., and James W. Watts, M.D., F.A.C.S., F.I.C.S., Professor of Neurological Surgery, George Washington University, Washington, D. C. Second edition. Cloth. $10.50. Pp. 598, with 156 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This edition of this monograph on psychosurgery is greatly enlarged over the first edition, which appeared in 1942. The authors' experience with the treatment of mental illnesses by surgery on the frontal lobes has been greatly extended. Only 80 patients had been operated on at the time of their first edition. They now have performed frontal lobotomy on 617 patients and transorbital lobotomy on 262 patients.

In the interval between the publication of the two editions of this monograph, various new techniques of psychosurgery have been devised, and operations on the frontal lobes have been used in the treatment of patients with intractable pain. The new techniques of removal of selected areas of the frontal cortex (topectomy), undercutting of the frontal cortex, thalamotomy, and open frontal lobotomy are discussed briefly. The authors have continued to use their original technique of frontal lobotomy. One of the authors, Dr. Freeman, has performed the majority of the transorbital operations. Dr. Watts expresses the opinion that any procedure involving cutting of brain tissue is a major surgical operation and should be performed only by those schooled in neurosurgical techniques, and that disability should constitute the indication for transorbital lobotomy, as well as for other types of psychosurgery.

The monograph is well written. Abstracts of case histories are scattered throughout the text. These, together with the numerous illustrations and tables, add greatly to its value. There are several hundred references to the important publications that have appeared on the subject since 1942. There is a brief but adequate index.

The authors have performed a monumental task in following the nearly 1,000 patients who have been subjected to operation. The operative procedures, management of the patient in the immediate postoperative period, and the treatment after discharge from the hospital are considered in detail. The final results, grouped according to diagnostic categories, are discussed fully and also presented in tabular form. Complications of the operations, fatalities, and unfavorable sequelae are discussed fully. Possible reasons for failure of the operations are considered, as well as the factors that are of importance in the determination of whether the operation is indicated and whether it is likely to be successful.

Psychosurgery is still a controversial subject. Ardent advocates and antagonists are still debating the subject. The final role of psychosurgery in the treatment of mental illnesses and in the relief of intractable pain has not been definitely settled. This edition of this monograph by the two physicians who have pioneered this work in this country and who have had the greatest experience in this field will always be a milestone and will serve as a guide to others who are seeking an ultimate solution to the problem.

Nitrous Oxide-Oxygen Anesthesia. By F. W. Clement, M.D. Third edition. Cloth. $6.50. Pp. 369, with 129 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1951.

The author is widely known as an authority on the subject because of his work and teaching. Nitrous oxide anesthesia is thoroughly discussed from the standpoint of pharmacology, physiology, and practical administration. The signs of anesthesia, the techniques of administration, and the dangers incident to the administration of anesthesia are clearly presented.

This edition has been considerably enlarged, and there is a more detailed discussion of important factors in the administration of nitrous oxide anesthesia. A chapter is devoted to the use of curare, and there is a discussion of the use of other anesthetic agents as a supplement to nitrous oxide. Because of the widespread interest in and use of combinations of nitrous oxide, curare, and thiopental (pentothal®) sodium, considerably more space might have been allotted to a discussion of this form of combined anesthesia. The characteristics of nitrous oxide anesthesia, as presented in this volume, are so modified by the use of combinations of drugs that new descriptions are called for.

This volume is also valuable, because it presents information on many subjects, other than nitrous oxide, of interest to the anesthesiologist. It discusses the classification of patients as to operative risk, premedication, and the causes, signs, and treatment of circulatory and respiratory disturbances during operation. Endotracheal anesthesia and the technical features of anesthetic gas administration are described. The importance of oxygen and abnormalities in oxygen and carbon dioxide levels are discussed. Anesthesia for dental operations is very well presented.

This volume is excellent because of its clarity of description and its wealth of detail. Some portions are primarily of historical interest. The book should be read and studied by all persons who administer anesthetics.

• The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Adsorption and Chromatography. By Harold Gomes Cassidy, Associate Professor in Chemistry, Yale University, New Haven. Volume V, Technique of Organic Chemistry. Arnold Weissberger, editor. Cloth. $7. Pp. 360, with illustrations. Interscience Publishers, Inc., 250 5th Ave., New York 1; 2a Southampton Row, London, W.C.1, 1951.

The stated objective of the book is to describe and explain by discussion of principles the various means by which adsorption may be used in organic chemistry for the separation of mixtures. This purpose is admirably achieved in spite of the enormous quantity of work in this field that has been reported in the literature. Limiting his discussion to types of manipulations and the principles involved rather than giving detailed procedures for specific separations, the author has been able to indicate the wide applicability of adsorption to organic separations. He has emphasized liquid-vapor, liquid-liquid, and liquid-solid interfaces, since they are of prime interest to the organic chemist. References to the literature on other interfaces are nevertheless given. Adsorbents, their properties and sources are discussed fully. Little discussion is included on biochemical implications, surface active agents, wetting, detergency, or industrial applications, although references to the literature are given where possible.

The subject of adsorption in the separation of mixtures is of such great importance to the chemist and biochemist that even a mediocre treatise on the subject would generate considerable interest. A work as comprehensive and lucid as this one will unquestionably become an essential of any serious chemical library.

Diarreas por deficiencia de la nutrición: Sprue y otros síndromes digestivo-anemicos similares. Por el Dr. Fernando Milanés Alvarez, profesor de la Facultad de medicina de la Universidad de la Habana. Cloth. Pp. 329, with 39 illustrations. Editorial Libreria Selecta, O'Reilly 357, La Habana, 1950.

In this volume, the author following a methodical order discusses the clinical characteristics for identification of the diarrheic syndromes due to deficiency of nutrition; its differential diagnosis with diarrheas not due to deficiency of nutrition; the importance of general information as to the habits of nutrition and pathological antecedents; the clinical aspect with symptomatology, subjective and objective, and the complementary laboratory examinations; radiological and endoscopic studies, and biopsies. There is a chapter on the differential diagnosis of the different types of diarrheas due to deficient nutrition with its anatomical and histological pathology, physiopathology, and etiopathogenesis. Later there is a chapter dealing with evolution, complications, prognosis, treatment, prophylaxis, and rehabilitation.

The work presented is based on studies carried out in Cuba on Cuban patients who follow a type of nutrition that differs from that prevalent in this country because of economic and climatic conditions. Nevertheless, the principles are the same, and the conclusions should prove worth while to the practitioner and the specialist in the field.

The language used throughout the book is Spanish, but at the end of the volume there is an extensive bibliography in which mention is made of numerous articles published in English. There are many illustrations, some in color, and numerous charts and statistics which complement the discussions.

My Six Convicts: A Psychologist's Three Years in Fort Leavenworth. By Donald Powell Wilson. Cloth. $3.50. Pp. 369. Rinehart & Company, Inc., 232 Madison Ave., New York 16, 1951.

The author of this book is a professor of psychology. He was formerly at the University of Redlands and is now at Los Angeles State College. He was asked by the United States Public Health Service to undertake a research project in drug addiction and criminality at Fort Leavenworth Penitentiary and for three years devoted himself to the study which forms the basis of the present book.

The book is written in seminarrative form. It is not a record of the research project, but is a "reminiscent impression of the humors, whimsies and tragedies" of his six convict assistants. It relates his winning the good will of the hardened and often vicious criminals, the obstacles he met, and the accomplishments. Although the names of the characters are fictitious, all the events he describes actually occurred. Just a few of these are the murder of a fellow convict under the very eyes of the guards, an attempted prison break when the convicts saved the author's life, and the time when a Negro convict hypnotized his guard, hanged himself with the guard's belt, was declared dead by a physician, and came out of his three day trance on the autopsy table as the knife was poised over him.

In addition, the book tells something of how a psychologist carries out his testing and the reasoning behind it. It also supplies information about penal conditions in this country. It contains both pathos and humor. Every page is good reading.

The Low Fat, Low Cholesterol Diet: What to Eat and How to Prepare It. By E. Virginia Robbin, Senior Dietitian, E. V. Cowell Memorial Hospital, University of California, Berkeley, and others. Introduction by Thomas P. Lyon, M.D., Research Associate in Medical Physics, Donner Laboratory, University of California, Berkeley, and John W. Gofman, Ph.D., M.D., Associate Professor of Medical Physics, Donner Laboratory, University of California, Berkeley. Cloth. $3.45. Pp. 371, with illustrations. Doubleday & Company, Inc., Garden City, New York; 14 W. 49th St., New York 20, 1951.

The growing concern which has developed recently relative to the relation of cholesterol intake and metabolism to atherosclerosis has created an unusual need for a reliable source of information about dietary sources of cholesterol and the practical management of low cholesterol diets. This need has been admirably filled by the volume "The Low Fat, Low Cholesterol Diet" by Dobbin, Lyon, and Gofman.

This book is written for both the physician and the layman by a group of capable dietitians and one physician. It is filled with useful information concerning the fat and cholesterol content of various foods and with dozens of carefully prepared menus which are applicable to conditions of slight, moderate, or extreme dietary restriction of fat or cholesterol, or both. The exact manner of use of special purpose foods, the sources of such foods, and the actual recipes for their use in the diet are all included. Indeed, it is impossible to imagine any combination of dietary circumstances related to the main problem under consideration that is not covered in its practical aspects in this volume. No attempt has been made to produce a textbook on cholesterol metabolism or on the pathology or clinical aspects of arteriosclerosis. The appendix does contain, however, a brief but reliable section on nutrition in general, sufficient for a consideration of the adequacy of special diets.

There is no obvious criticism of the book itself, but in regard to the underlying philosophy on which it is based, it is justifiable to point out that the validity of low cholesterol, low fat diets as a practical means for control of the atherosclerotic process remains to be proved. On the basis of present evidence, the genetically determined manner of handling cholesterol by the metabolic machinery of the person probably is of far greater importance than the magnitude of the exogenous source of that steroid compound. If in the future some practical way is devised by which cholesterol-susceptible persons may be identified, then a practical volume of this sort will take on added meaning, for it is clear that certain persons will show a pronounced slowing of vascular cholesterol deposition when their intake of that substance is restricted. To many others it apparently makes little difference. It is impractical, even if scientifically sound, to attempt to change the dietary habits of a whole population, at least until the evidence is more persuasive.

These considerations, however, do not detract from this excellent volume itself, and it is to be recommended without any qualifications to dietitians, physicians, and laymen who need dependable help in solving the practical problems of the low cholesterol diet.

Allgemeine und anorganische Chemie: Ein einfaches Lehrbuch auf neuzeitlicher Grundlage. Von Gerold Schwarzenbach, Professor an der Universität Zürich. Fourth edition. Cloth. 21.60 marks; $5.15. Pp. 474, with 107 illustrations. Georg Thieme, Diemershaldenstrasse 47 (14a) Stuttgart O; agents for U. S. A.: Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950.

This work seems to be simply and clearly written, well organized, and adequately illustrated. It gives almost equal space to an exposition of modern chemical theory and a description of the elements and their common compounds. The material covered is more extensive and the treatment is more thorough than one might expect in American elementary textbooks. Unlike some foreign books, it is indexed adequately.

Elements of Bacterial Cytology. By Georges Knaysi, Professor of Bacteriology, Cornell University, New York. Second edition. Cloth. $5. Pp. 375, with 169 illustrations. Comstock Publishing Company, Inc., 124 Roberts Place, Cornell Heights, Ithaca, New York, 1951.

This edition of Professor Knaysi's monograph, the first edition of which appeared in 1944, has been greatly expanded and revised to include new knowledge resulting from the current revival of activity in the cytology of microorganisms. The book can be recommended as indispensable background and reference reading for the serious and discriminating student of the subject, whether he be a mature investigator or graduate student.

Professor Knaysi's book is not clinically oriented. For the medical reader seeking orientation in microbiology, this treatise is recommended only with reservations arising from the following considerations. Biochemically the basic similarities of all living organisms, including bacteria, are well established. Recognition of fundamental biochemical processes common both to microorganisms and to the cells of higher organisms is proving exceedingly fruitful in that it permits analysis, through more experimentally controllable populations of microorganisms, of processes that can be verified as occurring in the metabolism of the cells of higher forms, including man. Appreciation of similar common elements in the structure and organization of the cells of bacteria and of higher forms is just now in process of emergence. The details are highly controversial. No general treatise, including Professor Knaysi's, could possibly keep abreast of this rapidly developing new insight. Areas of bacterial cytology in which the rapid chances in the subject have rendered obsolescent even the treatment in Professor Knaysi's recent monograph are as follows: the organization of the nucleus, nuclear division, sporulation, bacterial cytogenetics, the organization of the cytoplasm, the biology of spirochetes and bacterial flagella.

The very defects of the book are cogent evidence of the process of maturation which bacterial cytology is currently undergoing, and to which Professor Knaysi has contributed enormously through his personal investigations, his scholarly and critical reviews, and his teaching. "Elements of Bacterial Cytology" is illustrated well and profusely, and includes many original electron micrographs. The style is clear and readable and the bibliography valuable. The book is an essential contribution to its field. It should stimulate all concerned to seek clearer insight into this challenging subject.

Human Physiology. By Bernardo A. Houssay, M.D., Professor of Physiology, Buenos Aires, Argentina, and others. Translated by Juan T. Lewis, M.D., and Olive T. Lewis. Foreword by Herbert M. Evans, M.D. Cloth. $14. Pp. 1118, with 499 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1951.

This new textbook of physiology is edited by Houssay, well-known endocrinologist and Nobel laureate in physiology, and written by him and other South American physiologists. It gives a well-balanced presentation of the various parts of human physiology, without undue overemphasis of those areas of physiological research in which the writers are particularly interested. The book will be of great value to beginning medical students who find other standard textbooks too difficult. The book is amply illustrated, and each chapter is provided with a small number of additional references for further study. There is an extensive index. Printing and binding are excellent.

Methods of Vitamin Assay. Prepared and edited by Association of Vitamin Chemists, Inc. Second edition. Cloth. $5.50. Pp. 301, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1, 1951.

With the strides made in both vitamin technology and therapy and the advent of new vitamins, this edition of a widely accepted and used book is warmly welcomed. Assays for members of the vitamin B complex family, newly included in this edition, are those for pantothenic acid, pyridoxine, folic acid, biotin, vitamin B_{12}, and a chemical analysis for nicotinic acid (niacin). Both suggestions from interested persons and information from current literature have been utilized in the revision of the methods included in the first edition.

The chapter on vitamin B_{12} should be of special interest because of the world-wide attention which has been focused on this important newcomer to the field since the announcement of its discovery in 1948.

The book includes time-tried analytical procedures only. The methods included have been successfully applied to a variety of foods or other materials by several committee members.

The main merit of the book lies in the great job that has been done in the incorporation in one cover of those analytical methods that will be of most utility to the vitamin chemist and the inclusion of sufficient explanatory material with each method so that no difficulty should be experienced in application of the method, there being no necessity for recourse to the original source.

The Abnormal Pneumoencephalogram. By Leo M. Davidoff, M.D., Director of Neurological Surgery, Beth Israel Hospital, New York, and Bernard S. Epstein, M.D., Associate Radiologist, Jewish Hospital of Brooklyn, Brooklyn. Cloth. $15. Pp. 506, with 695 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1950.

This book is a fitting and valuable companion to "The Normal Encephalogram," by the same author. In the introduction, the technic, examination, and interpretation of plain roentgenograms of the skull are discussed. Following this is a chapter on pathology of brain tumors, which compresses some excellent photomicrographs and brief descriptions of the great majority of brain tumors into less than 20 pages.

The brain tumors are classified properly according to their anatomic location. Each group is covered in ideal fashion as follows: The introduction is a presentation of the clinical picture with the usual signs and symptoms. This is followed by a brief review of the literature; then the authors list their own material. The plain roentgenograms of the skull are discussed, and then the pneumoencephalographic studies, with the characteristic deformities taken up in detail. Positive and pertinent negative findings are summarized and the differential diagnosis discussed.

This excellent work on brain tumors accounts for at least 60% of the material in the text. There are two other sections. One, under the heading of Non-Neoplastic Tumors, covers subdural hematoma, brain abscess, syphilis of the brain, vascular anomalies of the brain, intracranial aneurysms, and cerebral hemorrhage and thrombosis. The second, titled Non-Tumorous Lesions of the Brain, includes lesions of the septum pellucidum; lesions of the aqueduct of Sylvius, spontaneous pneumocephalus; cerebral atrophy, agenesis of the corpus callosum, platybasia, Arnold Chiari malformation, meningoencephalocele and craniolacunia; congenital hydrocephalus; amaurotic family idiocy; optic chiasm and posterior fossa arachnoiditis; serous meningitis; encephalitis, encephalopathies and rare infections of the nervous system, and tuberous sclerosis. These subjects are discussed in the same manner as the brain tumors.

There is an excellent index of illustrative cases. The whole book is so arranged as to be most valuable to the neuroradiologist as a reference work, stressing as it does the anatomic approach to the problems of interpretation.

The Normal Encephalogram. By Leo M. Davidoff, M.D., Director of Neurological Surgery, Beth Israel Hospital, New York, and Cornelius G. Dyke, M.D. Third edition, revised by Leo M. Davidoff. Cloth. $6. Pp. 240, with 190 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1951.

As stated in the preface this book is chiefly concerned with encephalographic anatomy. It remains the outstanding work in this field, brief and easily readable. The addition of planigraphy has aided considerably in clarifying the anatomy of midline structures. There is little change in the organization of the material. Additional excellent illustrations have been included, and the bibliography is more extensive.

Under "General Considerations" are grouped history, indications and contraindications for encephalography, technique of encephalography, roentgen technique, and reactions to encephalography. Following are separate chapters, entitled "The Ventricles, Interventricular Foramina and Aqueduct of Sylvius," "The Cerebral Convolutions and Sulci," "The Subarachnoid Cisterns and Their Contents," and "Intracranial Structures and Their Related Fluid Spaces." This last chapter is of particular value in correlating certain solid structures with the overlying and adjacent air shadows as seen on the roentgenogram.

QUERIES AND MINOR NOTES

SLEEPING PILLS CONTAINING AN EMETIC

To the Editor:—*It has been suggested that some drug be incorporated in sleeping pills which would make the patient vomit if he took an overdose. What is that preparation called? What is the emetic most suitable for this purpose, and in what dosage is it used so it will not cause any symptoms in normal dosage but will cause vomiting in doses of a lethal nature? It seems like an excellent way of preventing suicide by overdoses of sedatives.* *H. Curtis Wood, M.D., Philadelphia.*

Answer.—Combinations of barbituric acid derivatives and an emetic drug, designed to produce emesis when dangerous dosage levels of the barbiturate are reached, have been on the market for two years or more. Mixtures of this type, containing ipecac as the emetic drug, have been supplied under such trade names as sed-ems® (a capsule sold by Wm. A. Spencer, Inc., Chicago, and stated to contain 100 mg. of pentobarbital sodium and 30 mg. of powdered ipecac), em kaps® (pentobarbital sodium and powdered extract ipecac) and em tabs® (phenobarbital plus powdered extract ipecac). The latter two preparations have been supplied by the Dahl Pharmacal Company of Minneapolis.

The report of the animal experiments of Miskimon and Miskimon (A Method for the Prevention of Suicidal Deaths Caused by the Barbituric Acid Derivatives, *Virginia M. Monthly* **77**:119 [March] 1950) suggests that zinc sulfate might be preferable to ipecac in such preparations. Ipecac is not free of systemic toxicity. It produces vomiting by a combination of central and local action. If the emetic component of such a drug combination must be absorbed in order to be effective, ample time will elapse for simultaneous absorption of much of the barbiturate. Zinc sulfate is faster in producing emesis, and, should no emesis occur, it is not absorbed.

In December 1949 the Council on Pharmacy and Chemistry gave consideration to a barbiturate-ipecac combination and offered the following objections to such mixtures: 1. Emetics such as ipecac are not harmless drugs but potential poisons, even though the amount included with ordinary hypnotic doses of the barbiturate probably would not injure the majority of patients. 2. It is questionable whether the emetic would accomplish the object intended, as toxic doses of barbiturates that are rapidly absorbed would probably narcotize the emetic center. 3. If the emetic is effective, vomitus might be aspirated into the bronchi of a partially narcotized patient and kill rather than save the patient.

THE FENESTRATION OPERATION

To the Editor:—*Does the fenestration operation for otosclerosis have any effect on auditory nerve degeneration? Is nerve deafness apt to occur in otosclerosis whether or not one has a fenestration operation?* *M.D., Pennsylvania.*

Answer.—A recent study suggests that a successful fenestration operation with a maintained hearing improvement may afford a partial protection against progressive auditory nerve degeneration. This finding, based on a study recently published by Adin and Shambaugh in the *Archives of Otolaryngology,* March, 1951, of 390 ears observed for five to 10 years, needs confirmation by other observers before it can be accepted conclusively. Theoretically, one would not expect the fenestration operation to have any effect on the underlying sclerotic lesion, including the auditory nerve degeneration which so often occurs in otosclerosis.

HAPTENS AND BLOCKING ANTIBODIES

To the Editor:—*Please discuss attempts to produce haptens to neutralize antibodies in the Rh-negative pregnant woman and explain blocking antibodies. Please give references to the literature.* *A. Pirrone, M.D., Cleveland.*

Answer.—The idea of preparing Rh hapten to neutralize Rh antibodies in sensitized Rh-negative women was first proposed in 1944 (Wiener, Sonn and Belkin: *J. Exper. Med.* **79**:235 [March] 1944). Belkin and Wiener (Demonstration of the Properties A, B, M, N, and Rh in Red Cell Stromata, *Proc. Soc. Exper. Biol. & Med.* **56**:214 [June] 1944) showed that the Rh factors, as well as the M-N and A-B factors, are located in the red cell stromas, but were unable to extract the Rh substance from the stromas. These observations have been confirmed (Calvin, Evans, Behrendt and Calvin: *Proc. Soc. Exper. Biol. & Med.* **61**:416 [April] 1946). Carter (*J. Immunol.* **61**:79 [Jan.] 1949) claimed to have isolated the Rh hapten in alcoholic extracts of red cells and asserted that injection of her preparation reduced the Rh antibody titer in vivo. Wiener (*J. A. M. A.* **141**:1330 [Dec. 31] 1949) and Unger (*Am. J. Obst. and Gynec.* **58**:1186 [Dec.] 1949) showed, however, that Carter's preparation was inert serologically both in vitro and in vivo. Recently Moskowitz, Dandliker, Calvin and Evans (*J. Immunol.* **65**:383 [Oct.] 1950) also reported their inability to confirm Carter's work. By a complicated physical procedure involving multiple separations from aqueous suspensions by high speed centrifugation, they obtained a water-soluble fraction which they designated as elinin, which contained the Rh and A and B factors from red cell stromas. The Rh activity of the elinin was destroyed after five minutes at 56 C., but the A activity was not diminished after 30 minutes at 56 C. Moreover, the Rh activity was rapidly lost even in sterile solutions in the refrigerator after as short a period as two weeks. Thus, this new technic is not suitable for the preparation of Rh hapten for clinical use. In summary, the claims of Carter are based on faulty observations and there is no immediate prospect of a practicable method of preparing Rh hapten; nor is there any assurance, should a method be devised for preparing Rh hapten, that such preparations would be effective in clinical work.

The term blocking antibody is applied to Rh antibodies that are incapable of clumping Rh-positive red cells in saline mediums. The earlier work on Rh typing was done with Rh-agglutinating serums active in saline mediums. When cases with clinical evidence of Rh sensitization were encountered in which Rh antibodies could not be demonstrated in the patient's serum by the usual agglutination technic, Wiener postulated the existence of a second type of Rh antibody capable of combining with Rh-positive cells in saline mediums but without clumping them. He devised a test (blocking test) for demonstrating these antibodies, and showed that, when Rh-positive cells are treated with serum containing strong Rh-blocking antibodies, they become coated by Rh antibody and can no longer be clumped by Rh-agglutinating serum. Later, the Rh-blocking antibodies were encountered independently by Race and Diamond, who pooled anti-Rh$_0$ and anti-rh' serums in an attempt to produce polyvalent anti-Rh'$_0$ serum. When the pooled serum still acted as anti-rh', they traced this to the presence of anti-Rh$_0$-blocking antibodies, which Race called "incomplete" Rh antibody. Subsequently, more sensitive and direct methods for demonstrating Rh$_0$-blocking antibodies were developed, namely, the conglutination test of Wiener, the antiglobulin test of Coombs and co-workers and the tests with trypsinated red cells of Morton and Pickles. However, all these tests appear to detect the same antibody, which, because of its in vitro and in vivo behavior, is designated univalent Rh antibody to distinguish it from the Rh agglutinins, which are designated bivalent antibodies. This concept, of Rh-blocking antibodies as univalent antibodies, explains their blocking action, and it would be expected that univalent antibodies are of smaller molecular size than bivalent or agglutinating antibodies. In fact, Wiener has shown (*Ann.*

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

Allergy 6:293 [May-June] 1948) that univalent-blocking antibodies readily pass through the intact placenta while bivalent antibodies (agglutinins) are held back by the normal placental barrier. Thus, it is the blocking or univalent antibody that causes erythroblastosis rather than the agglutinating antibody as originally postulated by Levine. Nowadays, in antenatal Rh antibody tests, therefore, emphasis is placed on tests to detect univalent Rh antibodies rather than Rh agglutinins. Diagrams to explain the action of blocking antibodies in the blocking test, conglutination test, antiglobulin test and test with trypsinated cells have been prepared by Wiener (Rh Glossary, *Lab. Digest* **6**:1 [Nov.] 1950).

LOCALIZED FAT ACCUMULATIONS

To the Editor:—*A 19 year old girl has abnormal distribution of fat from the waist line to 4 inches above the knees. It has spared the buttocks but is very thick in the lateral aspects of the hips and thighs. Her breasts are normal, her basal metabolic rate is + 4 and urine and blood findings are normal. She has extremely irregular menses with severe cramps before and during the menstrual period. Her liver is palpable 1 cm. below the costal margin. She has had infectious hepatitis. She has been on a strict diet for two years (2,000 calories), although the strictness of the diet might be on paper only. In two years she has gained 24 pounds. She has coarse hair on the body and is developing a mustache. Please tell me what to look for. Is there any treatment? Would you consider a pituitary tumor?* *James A. Craig, M.D., Naples, Fla.*

Answer.—While this patient has a number of the signs and symptoms of an endocrine disorder, such as localized fat accumulation between the hips and knees, irregular menstrual cycles and hirsutism, it is suggested that for the present this be treated as a case of exogenous obesity in view of the impracticability of a detailed endocrine analysis in your locality. It is suggested that she be placed on a 1,000 calory diet, with the use of appetite-curbing drugs, such as the amphetamines, if necessary. The dosage of such drugs would be preferably 5 mg. of racemic amphetamine sulfate or phosphate three times a day, one hour before meals. If necessary the dosage may be increased at those times during the day when the patient has difficulty with food restriction. A small dose of a barbiturate may be required with the evening dose temporarily. It is probable that with weight loss the menstrual cycle will become normal. Even with the irregular menses it would seem that the patient is ovulating, since functional dysmenorrhea is usually associated with ovulation. In considering a pituitary tumor, one might find this type of fat distribution if there were involvement of the hypothalamus, but this is more often than not associated with amenorrhea. It is advised, however, that a roentgenogram of the skull be obtained to rule out the possibility of this lesion.

HEART DISEASE AND RADIOACTIVE IODINE

To the Editor:—*An Arizona newspaper, on about March 1, 1951, published an article referring to work done by Drs. Herrman L. Blumgart and A. Stone Freedberg, of Harvard Medical School, in which they used radioactive iodine in the treatment of angina pectoris. Has anything been published in medical literature on this subject?*

George A. Barnett, M.D., Riverside, Ill.

Answer.—A comprehensive report of the treatment of patients with chronic heart disease who have normal thyroid functions by Blumgart and associates has appeared in *Circulation* (1:1105, 1950). Other articles by these authors are as follows: Treatment of Euthyroid Cardiac Patients by Producing Myxedema with Radioactive Iodine (*Proc. Soc. Exper. Biol. & Med.* **67**:190, 1948) and The Treatment of Euthyroid Cardiac Patients with Intractable Angina Pectoris and Congestive Failure with Radioactive Iodine (*J. Clin. Endocrin.* **10**:1270, 1950).

The application of this method of treatment has been reserved for those who have remained incapacitated because of severe attacks of angina pectoris despite the use of all accepted medical measures. This method of treatment is being employed in several centers where radioactive iodine is available and is said to be helpful in selected cases. A report from the University of Pennsylvania has appeared in the *Pennsylvania State Medical Journal*, April 1951.

IMMUNIZATION AGAINST TETANUS

To the Editor:—*A boy now aged 11 was given an injection of tetanus toxoid by another physician in 1946, following which it is said he was unconscious for 24 hours. He also has a history of fever and local swelling from an injection of diphtheria toxoid given at the age of 4. There is asthma and hay fever on both sides of his family; he too has asthma. Recently he came in for immunization against tetanus. Tetanus toxoid, fluid, was tried in the following ways: 1. An injection of 0.02 cc. was given intradermally and resulted in the development locally of a wheal about 10 by 15 mm. surrounded by an area of erythema about 4 cm. in diameter. 2. A few days later he was given the same amount subcutaneously. Two days after this he was found to have an area of redness and swelling about 5 by 10 cm. surrounding the site of the injection. The usual single dose of this material is 0.5 cc. This child is said to be sensitive to penicillin. What efforts, if any, should be made to immunize this boy against tetanus? It was learned that at one time he had been given tetanus antitoxin for an injury with no ill effects.* *M.D., Florida.*

Answer.—This patient's blood serum should be titrated so that the existing level of immunity against both tetanus and diphtheria may be determined. If the injection given in 1946 was alum-precipitated tetanus toxoid, it is probable that this acted as a sensitizing dose, so that later injections could function in the manner of booster doses. The intracutaneous injection of amounts of tetanus toxoid as low as 1/250th cc. can elicit a satisfactory immunologic response in adequately prepared subjects. Moreover, an interval of five to 10 years does not militate against satisfactory response to recall injections of such small magnitude. Presuming that the usual initial dose, followed by repeated small intracutaneous injections, in this subject has not resulted in an adequate level of immunity, it is recommended that repeated minute volumes of tetanus toxoid (0.01 cc. or less) at intervals of one or more weeks, the number to be determined by blood titrations, be utilized. The Children's Bureau, Washington, D. C., has a list of laboratories engaged in studies on active immunization against tetanus. The mailing of specimens of blood serum to any one of these laboratories would assist in expediting immunization of your patient.

VAGINAL ORGASM

To the Editor:—*Please explain what is meant by the term "vaginal orgasm."* *G. Lombard Kelly, M.D., Augusta, Ga.*

Answer.—A distinction has been made between clitoral orgasm and vaginal orgasm, but this distinction is controversial because some authorities deny that a "vaginal orgasm" exists. J. P. Greenhill (Office Gynecology, ed. 5, Chicago, Year Book Publishers, 1948, p. 123) says, "I should like to emphasize a point about which almost nothing has appeared in gynecologic literature. This is that in women there are actually two sexual organs. The first is the clitoris, which plays the dominant role in childhood and in masturbation during adulthood. The second organ is the vagina, which psychologically is unimportant until puberty. Whereas in the child the clitoris can and does give sexual satisfaction, in the normal adult woman it is the vagina which is the principal sexual organ. In frigid women, however, the transfer of sexual excitement and satisfaction from the clitoris to the vagina does not take place.

"E. Bergler (Psychiat. Quart. 18:374 [July] 1944) maintains that a typically frigid woman suffers not from a deficiency of the libido but from a neurosis, that is, an illness of the unconscious. For this reason, hormone therapy is unsuccessful in typical cases. Bergler believes that the involuntary contraction of pelvic and perineal muscles at the end of the sex act is the one and only sure criterion that a man can use to determine whether a woman is frigid. Although the absence of glandular lubricating secretion during coitus is a sure sign of frigidity, the converse is not necessarily true; presence of the secretion does not exclude the possibility that frigidity in a mild form may exist."

Helene Deutsch in "The Psychology of Women" (Grune & Stratton, 1944, p. 233) says, "The awakening of the vagina to full sexual functioning is entirely dependent upon the man's activity; and this absence of spontaneous vaginal activity constitutes the physiologic background of feminine passivity. The competition of the clitoris, which intercepts the excitations unable to reach the vagina, and the genital trauma then create the dispositional basis of a permanent sexual inhibition, i. e., frigidity."

Sandor Rado, in his chapter on "An Adaptational View of Sexual Behavior" in "Psychosexual Development in Health and Disease" (edited by Paul H. Hoch and Joseph Zubin, Grune & Stratton, 1949), says (p. 162), "Physiologically, coition may be described as a patterned sequence of mutual stimulatory activities designed to elicit the reflex of orgastic peristalsis in both male and female. Orgastic peristalsis of the penile urethra effects the ejection of the semen; orgastic peristalsis of the vaginal walls facilitates this function by 'milking' the penis. The spread of excitation to adjacent structures and beyond may involve muscles of the entire body in orgastic convulsions, thereby producing a generalized "push and pull" toward the union of sperm and egg. Orgastic peristalsis is the insemination phase of reproduction."

Gustav Bychowski, in his chapter on "Some Aspects of Psychosexuality in Psychoanalytic Experience," says (page 200), "As a manifestation of feminine sexuality the difference between the vaginal and the clitoral orgasm is of paramount importance. In cases where only the latter is possible there is always a deep denial of the feminine role and a morbid masculine identification."

HELIUM AND ALUMINUM WELDING

To the Editor:—*In aluminum welding operations helium is blown onto the metal around the electric arc to facilitate the welding quality. Certain workers have complained of a "big head," and others of "pains in the chest." Would the inhalation of helium cause these "symptoms?"* *M.D., Illinois.*

Answer.—Both helium and argon arcs, improperly used, may produce physiological damage not produced by ordinary atmospheric electroarcs but not necessarily more injurious. Oxygen being essentially absent, neither nitrogen oxides nor metallic oxides are produced. In the absence of an atmospheric shield that absorbs ultraviolet rays near to the arcing area, more ultraviolet rays reach the general atmosphere. Since oxygen is absent from the arc point, ozone is not there created but is created in those zones adjacent to the welding area in which the oxygen of the atmosphere is present. Ozone in a concentration of 1 ppm has been detected around heli-arc welding, and this level may be physiologically significant. There is reason to believe that ozone formed along with nitrogen oxides behaves more actively as an irritant than when ozone is formed alone, but synergistic actions may be involved. The unadmixed ozone, a less immediate irritant, is said to cause less obvious symptoms, such as chest oppression. No proper use of the noble gas arcs will lead to oxygen deficiency. Seventy-five per cent mixtures are deliberately introduced into artificial atmospheres designed for breathing. However, no arc welding should be conducted in closely confined spaces without adequate protection of the worker. The resulting oxygen deficiency would characterize any form of welding, including helium. Helium is an inert gas, becoming important in respiration only when the quantity present displaces oxygen below that level requisite to normal respiration.

HAY FEVER AND CORONARY DISEASE

To the Editor:—*A 46 year old patient had a coronary occlusion and myocardial infarction four months ago. I would like to give him pyribenzamine® in the spring, which had given him good relief for hay fever in previous seasons, if not contraindicated. Would other histaminics be preferable?*

Elizabeth G. Brings, M.D., Cumberland, Md.

Answer.—There is apparently no evidence of a deleterious effect on the coronary circulation from antihistaminic drugs. Tripelennamine (pyribenzamine®) hydrochloride is probably as satisfactory as any, and if it has been used in the past without untoward symptoms there is no reason why it may not be repeated this year, despite the myocardial infarct of four months ago.

RHEUMATIC FEVER AND INFLUENZA

To the Editor:—*A 41 year old woman with rheumatic heart disease, who developed rheumatic pleuromediastinitis with bilateral, pleural effusion, auricular fibrillation, low grade fever, and chest pain which required either narcotics or meperidine hydrochloride several times a day for relief, showed no amelioration of signs or symptoms for two months. She then had an attack of influenza, epidemic in this area this winter. During the first day of this superimposed illness, the chest pains ceased, and in less than a week most of the pleural effusion had been absorbed. The influenza went through the usual stages observed in this epidemic—fever, sore throat, nasal catarrh, bronchitis and cough with greenish yellow sputum. Have other physicians observed instances in which the course of active rheumatic fever has been influenced by an attack of influenza?* *Max Dobrin, M.D., Miami Beach, Fla.*

Answer.—Cases are on record in which there is a temporary amelioration of active arthritis, rheumatic or otherwise, during active infections of other sorts or indeed during infarction, but there are no adequate statistics about this phenomenon as yet. Whether the spontaneous (increased endogenous) production of cortisone by the body in response to the acute complicating disturbance may be responsible for this is not known.

HISTAMINE AND HEADACHES

To the Editor:—*I would appreciate information concerning histamine desensitization for headaches: (1) type of product to be used, (2) dosage schedule and (3) duration treatment may be given and (4) contraindications for using histamine.*

M.D., South Dakota.

Answer.—Experimental and clinical observations indicate clearly that, by repeated injections of histamine, only a slight, if any, increased tolerance to histamine is produced. There is certainly no evidence for the claim of histamine desensitization. Histamine treatment may possibly be effective in some instances of headache, but the basis of such results is not understood. There are many techniques for the use of histamine and different routes of administration. One of the commonest procedures is as follows: Histamine diphosphate or hydrochloride or other histamine salt is used. The initial dose is 0.1 cc. of a 1:100,000 dilution. Injections are given frequently, at first daily or twice daily. Increments of about 25 to 50 per cent are made until the patient shows evidence of a reaction (headache, flushing of the face). After two or three weeks of frequent injections the intervals are lengthened to every other day and finally to once a week. The usual duration of treatment is two to three months. The contraindications for histamine injections are cardiovascular disease, peptic ulcer and some types of allergy.

EKG PATTERN IN CORONARY INSUFFICIENCY

To the Editor:—*Do electrocardiographic leads taken at the left sternoclavicular junction or the left supraclavicular space demonstrate coronary insufficiency? If so, what is the pattern?*

F. C. Ganyard, M.D., Wooster, Ohio.

Answer.—A V lead from the sternoclavicular junction or the supraclavicular groove is, theoretically, expected to reflect potentials derived mainly from the cavities of both auricles and ventricles. However, depending on the anatomic and/or "electrical" position of the heart, the type of thorax, and other factors, the resultant electrocardiographic pattern may represent a mixture of endocardial and epicardial potentials, the latter derived from various surface areas of the heart. Thus, a QS, Qr, qSr, or other combinations may be obtained, usually paired with an inverted T wave.

Acute or chronic coronary insufficiency will produce S-T-T variations depending on (*a*) the part of the heart which is mainly reflected in the lead under question and (*b*) the localization of the anatomic or functional lesion within the myocardium. The resultant pattern of coronary insufficiency may, therefore, consist of S-T elevation or S-T depression, and of upright T waves as well as of inverted T waves. Neither or both atypical leads may provide more or better evidence of coronary insufficiency than a routine electrocardiogram including standard leads, aV limb leads and precordial leads in the six standard positions.

NUMBNESS AND TINGLING OF FINGERS

To THE EDITOR:—*Please send information on "numbness and tingling of fingers of the upper extremity in middle age persons on arising in the morning."*

Herbert A. Mulholland, M.D., New York.

ANSWER.—Numbness and tingling of fingers is a frequent complaint and may arise from a variety of causes. The fact that t occurs on arising would indicate that its cause is not circulatory, although the correspondent does not state whether the symptom lasts throughout the day or subsides with motion. Arthritis and periarthritis of the small joints must be looked for. Neuritis due to vitamin deficiency, excessive alcoholic intake, or other toxic poison, such as lead or arsenic, must be considered. Pressure on the nerve trunks due to cervical rib, anterior scalenus muscle, cervical disk, or osteoarthritis of the spine is by far the most frequent cause of such complaints. Neurologic disorders of the cord and of the central nervous system must be excluded. If the fingers are not only numb but cold and cyanotic and the palpable arteries pulsate, arteriolar sclerosis may be present. Nervous fatigue and emotional tension often cause numbness and tingling in different parts of the body.

DAMAGE FROM TOXIC INDUSTRIAL SUBSTANCES

To THE EDITOR:—*According to J. A. Zapp Jr. (Human Biol.* **19***:27, 1947), an early variation in the health of an industrial worker may be detected by frequent blood pressure readings. It is stated a diastolic rise and blood pressure index change are expected with the worker experiencing a toxic accumulation. Has this work been confirmed and would this be a method of value in the detection of early absorption of mercury or dimethylformamide?*

Barnwell R. Baker, M.D., Waynesboro, Va.

ANSWER.—Foulger and his associates have long maintained that demonstrable vascular deviations constitute the earliest indication of damage from toxic substances found in industry and that such changes are nearly universal. The patterns encountered are not constant and vary with the extent or degree of exposure. The deviations are not profound, and the examinations require exactness. One requisite appears to be that the group of workmen tested are so accustomed to cardiovascular examinations that emotional responses would be no more likely to arise than from the commonplace lacing of shoes. Manifestly this will not usually be true for occasional examinations. For extended studies the method invites wide utilization. For the emergency examination of groups of workmen, practical difficulties may arise. Opportunity for application after exposure to the two substances mentioned is dependent on the universality of the response said to occur. It may be too early to accept universality in any phenomena of this character. Repeatedly, Foulger has observed that fatigue, malaise, malnutrition, exertion, alcohol, and some medicaments induce the same cardiovascular manifestations as industrial chemicals.

REACTIONS TO PENICILLIN

To THE EDITOR:—*A patient, whom I have been treating with 100,000 units of penicillin three times daily by the aerosol method and 300,000 units of procaine penicillin parenterally daily for chronic bronchiolitis and bronchiectasis, developed a magenta tongue which "burned" and mild cheilosis after about nine days of therapy. The patient was also receiving small doses of codeine sulfate to control an exasperating cough. Did the penicillin therapy, which, I may add, was accompanied by multivitamin capsules three times daily, cause a riboflavin deficiency?*

J. B. Wager, M.D., Bronx.

ANSWER.—In about 6 per cent of patients receiving penicillin aerosol therapy there will develop one or more of the following reactions: burning of tongue and mucous membranes, black tongue, inflammation of tongue and mucous membranes, cheilosis and in some rare instances, generalized urticaria. The majority of these reactions are believed to be due to local (contact) penicillin sensitivity. The manifestation of a black tongue is thought to be due to predominance of other organisms which appear after the penicillin-sensitive organisms are diminished as a result of aerosol therapy. This type of black tongue is not due to a riboflavin deficiency.

BERYLLIUM POISONING

To THE EDITOR:—*A metallurgical firm is about to begin a process in which wire brush abrasion of an alloy of 2 per cent beryllium and 98 per cent copper is employed. The dust is heavy and immediately settles to the floor, where it is oiled and promptly removed. What hazards are likely to arise? Should the workers be required to wear masks?*

Leonard W. Hill, M.D., Attleboro, Mass.

ANSWER.—Beryllosis is at present a threat because of lack of precise information as to circumstances leading to poisoning. In a few instances fatal involvement has followed minute trace exposure. But some entire groups have undergone exposure at high levels without apparent deleterious effects. Individual susceptibility is pronounced. Cases have arisen from the founding of alloys of the character mentioned, and it is believed that at least one case ensued after the mere cutting of alloy rods. It may not be assumed that no fine dust will be produced in a wire brush operation or that the fine dust will not oxidize. Both lung and cutaneous lesions are potentialities. Well functioning and well maintained exhaust units may be requisite. In addition, the wearing of suitable respirators may be necessary. The final test is the absence of beryllium in the atmosphere as breathed. Toward the best planning, it is suggested that the chief of the Laboratory Division of Occupational Hygiene of Massachusetts Department of Labor and Industries be consulted as to plans or installations.

ALLERGIC DISEASES IN ISRAEL

To THE EDITOR:—*In Queries and Minor Notes in* THE JOURNAL *of March 10, 1951 (page 773) Dr. Aubie Portigal asks for literature on the incidence of allergic diseases in Israel, especially bronchial asthma. Your answer that "no figures have been published on incidence" takes no notice of my article "Allergic Diseases in Palestine," published in* Harofe Haivri *(2:70, 1946). On the basis of statistical figures of the General Sick Fund (covering then one third of the Jewish population in Palestine) it has been found that during the years 1936-1944 0.98% of all new patients suffered from bronchial asthma. This percentage proves that bronchial asthma is as common in Israel as in other countries, including the United States. Doctors who have practiced previously in Europe maintain that the incidence of asthma in Israel is even higher than in other countries. This might be due to the fact that the greatest part of the population are immigrants, thrown into new climatic conditions and exposed to new plants and foods. A special problem in this country is the high incidence of bronchitis spastica among children up to the age of 3 to 4 years.*

Contrary to your opinion, I consider the climate here generally unfavorable for asthma, especially in coastal regions. Practically, this question has to be decided for every patient individually.

N. Lass, M.D.,
Hadassa Municipal Hospital, Tel-Aviv.

FOUR OPERATIONS FOR GALLSTONES

To THE EDITOR:—*In Queries and Minor Notes in* THE JOURNAL, *May 19, page 297, is a question about the prevention of gallstones in a patient who had been operated on four times for stones in the common duct. The answer failed to mention that excessive hemolysis is of prime importance in the formation of gallstones. Either congenital or acquired hemolytic anemia should be suspected in such a case, especially if the patient was a male or if the first attack of biliary colic occurred in a young person. In such cases, one should search carefully for splenic enlargement, by physical examination and, in case of doubt, by roentgen visualization. In addition, the various laboratory studies that indicate increased hemolysis or increased fragility of the erythrocytes should be employed. It should be remembered that hyperhemolysis may occur in paroxysms, so that at times the patient may show neither jaundice nor anemia, though these may appear at subsequent examinations. In cases of hemolytic anemia, splenectomy may be the best prevention of further gallstone formation.*

Ravenna, M.D., 104 S. Michigan Ave., Chicago 3.
